ECT*, Trento, Italy, May 15-19, 2023

- Introduction
- S-matrix and general jet kinematics
- Back-to-back limit and quark TMD
- Suppressing background processes
- Discussion: Consistent high-energy expansion in powers?

TMD vs CGC: from gluons to quark

For a process with a hard \mathbf{P} and a not so hard \mathbf{k} transverse momenta:

- TMD factorization: leading power (twist 2) in the limit $|\mathbf{k}| \ll |\mathbf{P}| \sim \sqrt{s}$
- CGC result: leading power (eikonal) in the limit $|\mathbf{k}| \sim |\mathbf{P}| \ll \sqrt{s}$

Consistency of both approaches shown in the double limit

$|\mathbf{k}| \ll |\mathbf{P}| \ll \sqrt{s}$, with gluon TMDs (Dominguez, Marquet, Xiao, Yuan, 2011) or low x sea quark TMDs (Marquet, Xiao, Yuan, 2009)

Gluon-driven TMDs dominant in this double limit because the target is described by a gluon background field $\mathcal{A}^-(x)$ in the (eikonal) CGC

Quark background field of the target should be included as well **beyond the eikonal limit.**

\Rightarrow Possibility to recover the quark TMDs from (non-eikonal) CGC, including valence?

Power counting for the quark background field $\Psi(z)$

- Under a boost of the target of parameter γ_t along the "–" direction, a current associated with the target should behave as

$$J^-(z) \propto \gamma_t, \quad J^j(z) \propto (\gamma_t)^0, \quad J^+(z) \propto (\gamma_t)^{-1},$$

- The quark background field of the target can be split as $\Psi(z) = \Psi^{(-)}(z) + \Psi^{(+)}(z)$, with

$$\Psi^{(-)}(z) \equiv \frac{\gamma^+ \gamma^-}{2} \Psi(z), \quad \Psi^{(+)}(z) \equiv \frac{\gamma^- \gamma^+}{2} \Psi(z).$$

Then, the components of the background quark current write

$$\begin{aligned} \overline{\Psi}(z) \gamma^- \Psi(z) &= \overline{\Psi^{(-)}}(z) \gamma^- \Psi^{(-)}(z), \\ \overline{\Psi}(z) \gamma^j \Psi(z) &= \overline{\Psi^{(-)}}(z) \gamma^j \Psi^{(+)}(z) + \overline{\Psi^{(+)}}(z) \gamma^j \Psi^{(-)}(z), \\ \overline{\Psi}(z) \gamma^+ \Psi(z) &= \overline{\Psi^{(+)}}(z) \gamma^+ \Psi^{(+)}(z). \end{aligned}$$

Under a boost of the target, the projections $\Psi^{(-)}(z)$ and $\Psi^{(+)}(z)$ should thus scale as

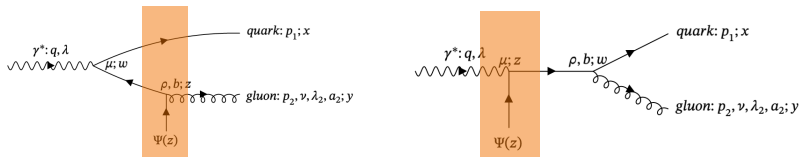

$$\Psi^{(-)}(z) \propto (\gamma_t)^{\frac{1}{2}}, \quad \Psi^{(+)}(z) \propto (\gamma_t)^{-\frac{1}{2}},$$

⇒ **Let us keep only the leading components $\Psi^{(-)}(z)$ of $\Psi(z)$**

See also Kovchegov *et al.* (2016–2023), and Chirilli (2019).

Contributions to $\gamma^* \rightarrow qg$ dijets from quark background

qg dijet production in DIS: a simple process sensitive to the quark background beyond eikonal CGC

$$S_{\gamma^* \rightarrow q_1 g_2}^{\text{bef}} = \lim_{x^+, y^+ \rightarrow +\infty} \int_{\mathbf{x}, \mathbf{y}} \int_{x^-, y^-} e^{ip_1 \cdot x} \bar{u}(1) \gamma^+ e^{ip_2 \cdot y} \epsilon_\nu^{\lambda_2}(p_2)^* (-2p_2^+) \times \int_{w, z} e^{-iq \cdot z} \epsilon_\mu^\lambda(q) G_F^{\nu\rho}(y, z)_{a_2 b} S_F(x, w) (-iee_f) \gamma^\mu S_F(w, z) (-ig) \gamma_\rho t^b \Psi(z),$$

$$S_{\gamma^* \rightarrow q_1 g_2}^{\text{in}} = \lim_{x^+, y^+ \rightarrow +\infty} \int_{\mathbf{x}, \mathbf{y}} \int_{x^-, y^-} e^{ip_1 \cdot x} \bar{u}(1) \gamma^+ e^{ip_2 \cdot y} \epsilon_\nu^{\lambda_2}(p_2)^* (-2p_2^+) \times \int_{w, z} e^{-iq \cdot z} \epsilon_\mu^\lambda(q) G_{F,0}^{\nu\rho}(y, w)_{a_2 b} S_{F,0}(x, w) (-ig) \gamma_\rho t^b S_F(w, z) (-iee_f) \gamma^\mu \Psi(z)$$

Propagators from inside to outside a gluon background

Eikonal quark propagator from y (inside the target) to x (after the target):

$$S_F(x, y) \Big|_{\text{Eik.}}^{\text{IA,q}} = \int \frac{d^2\mathbf{p}}{(2\pi)^2} \frac{dp^+}{(2\pi)} \frac{\theta(p^+)}{2p^+} e^{-ix \cdot p} (\not{p} + m) \mathcal{U}_F(+\infty, y^+; \mathbf{y}) \left[1 - \frac{\gamma^+ \gamma^i}{2p^+} i \overleftarrow{\mathcal{D}}_{\mathbf{y}^i}^F \right] e^{iy^- p^+} e^{-iy \cdot \mathbf{p}}$$

Eikonal quark propagator from y (inside the target) to x (before the target):

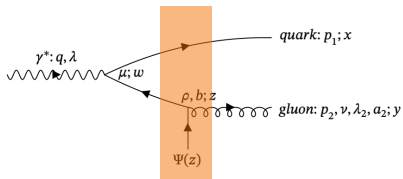

$$S_F(x, y) \Big|_{\text{Eik.}}^{\text{IB,q}} = \int \frac{d^2\mathbf{p}}{(2\pi)^2} \frac{dp^+}{(2\pi)} \frac{\theta(p^+)}{2p^+} e^{ix \cdot p} (\not{p} - m) (-1) \mathcal{U}_F^\dagger(y^+, -\infty; \mathbf{y}) \left[1 + \frac{\gamma^+ \gamma^i}{2p^+} i \overleftarrow{\mathcal{D}}_{\mathbf{y}^i}^F \right] e^{-iy^- p^+} e^{iy \cdot \mathbf{p}}$$

Eikonal gluon propagator from y (inside the target) to x (after the target):

$$G_F^{\mu\nu}(x, y) \Big|_{\text{Eik.}}^{\text{IA,g}} = \int \frac{d^2\mathbf{p}}{(2\pi)^2} \frac{dp^+}{(2\pi)} \frac{\theta(p^+)}{2p^+} e^{-ix \cdot p} \left[-g^{\mu j} + \frac{\mathbf{p}^j}{p^+} g^{\mu+} \right] \mathcal{U}_A(+\infty, y^+; \mathbf{y}) \left[g_j^\nu + \frac{g^{\nu+}}{p^+} \left(\mathbf{p}^j + i \overleftarrow{\mathcal{D}}_{\mathbf{y}^j}^A \right) \right] e^{iy^- p^+} e^{-iy \cdot \mathbf{p}}$$

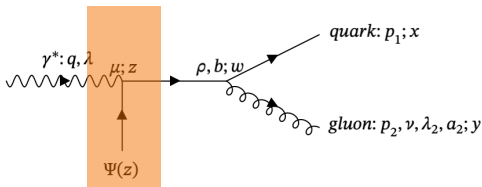

Contribution with γ^* splitting before the target

$$S_{\gamma T, L \rightarrow q_1 g_2}^{\text{bef}} = i e e_f g 2\pi \delta(p_1^+ + p_2^+ - q^+) \int_{\mathbf{v}, \mathbf{z}} e^{-i\mathbf{v} \cdot \mathbf{p}_1 - i\mathbf{z} \cdot \mathbf{p}_2} \int \frac{d^2 \mathbf{K}}{(2\pi)^2} \frac{e^{i(\mathbf{v}-\mathbf{z}) \cdot \mathbf{K}}}{[\mathbf{K}^2 + m^2 + \frac{p_1^+ p_2^+}{(q^+)^2} Q^2]} \\ \times \bar{u}(1) \frac{\gamma^+ \gamma^-}{2} \Gamma_{T, L}^{\text{bef}} \int_{z^+} U_A(+\infty, z^+; \mathbf{z})_{a_2 b} U_F(\mathbf{v}) U_F^\dagger(z^+, -\infty; \mathbf{z}) t^b \Psi(z^+, \mathbf{z})$$

with

$$\Gamma_L^{\text{bef}} = 2 \frac{p_1^+ p_2^+}{(q^+)^2} Q \varepsilon_{\lambda_2}^{j*} \gamma^j \quad \Gamma_T^{\text{bef}} = \varepsilon_\lambda^i \varepsilon_{\lambda_2}^{j*} \left\{ \mathbf{K}^l \left[\left(\frac{p_1^+ - p_2^+}{q^+} \right) \delta^{il} - \frac{[\gamma^i, \gamma^l]}{2} \right] + m \gamma^i \right\} \gamma^j$$

Similar to the case of $\gamma^* \rightarrow q\bar{q}$ dijet production in the the dipole picture/CGC at eikonal accuracy, but with a different color structure

Contribution with γ^* conversion inside the target

$$S_{\gamma_T \rightarrow q_1 g_2}^{\text{in}} = i \frac{e e_f g 2\pi \delta(p_1^+ + p_2^+ - q^+)}{\left[\left(\mathbf{p}_1 - \frac{p_1^+}{p_2^+} \mathbf{p}_2 \right)^2 + m^2 \right]} \int_{\mathbf{z}} e^{-i\mathbf{z} \cdot (\mathbf{p}_1 + \mathbf{p}_2)} \bar{u}(1) \frac{\gamma^+ \gamma^-}{2} \Gamma_T^{\text{in}} \int_{z^+} t^{a_2} U_F(+\infty, z^+; \mathbf{z}) \Psi(z^+, \mathbf{z})$$

with

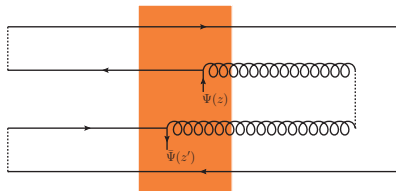

$$\Gamma_T^{\text{in}} = \varepsilon_{\lambda_2}^{l*} \varepsilon_{\lambda}^j \left\{ \left[\mathbf{p}_1^i - \frac{p_1^+}{p_2^+} \mathbf{p}_2^i \right] \left[- \left(\frac{2p_1^+ + p_2^+}{p_2^+} \right) \delta^{il} + \frac{[\gamma^i, \gamma^l]}{2} \right] + m \gamma^l \right\} \gamma^j$$

Note: $S_{\gamma_L \rightarrow q_1 g_2}^{\text{in}} = 0$ at NEik in Light-cone gauge, because $\not{\epsilon}_L(q) \Psi^{(-)}(z) = \frac{Q}{q^+} \gamma^+ \Psi^{(-)}(z) = 0$.

Color operators at cross section level

From the two diagrams contributing to the S-matrix, one can calculate the cross section for general kinematics of the jets.

→ Various color structures are obtained at cross section level:

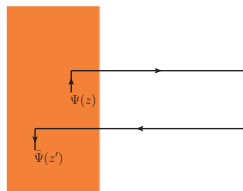

From the square of the diagram with splitting before the target:

Quadrupole with quark background field insertions, converting from fundamental to adjoint a portion of the quadrupole.

Color operators at cross section level

From the two diagrams contributing to the S-matrix, one can calculate the cross section for general kinematics of the jets.

→ Various color structures are obtained at cross section level:

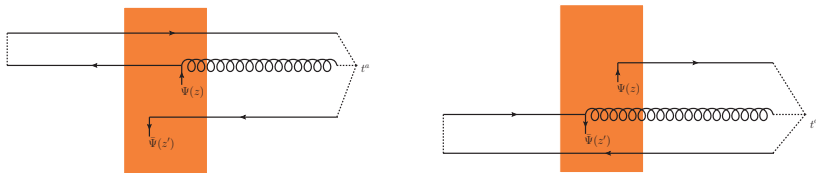

From the square of the diagram with splitting inside the target:

Quark bilinear with future staple.

Color operators at cross section level

From the two diagrams contributing to the S-matrix, one can calculate the cross section for general kinematics of the jets.

→ Various color structures are obtained at cross section level:

From the interference of the two diagrams:

More exotic decorated multipole operators with quark field insertions!

Back-to-back jets: *inside* diagram

Back-to-back limit of dijets are conveniently expressed in terms of:

(dijet momentum imbalance) $\mathbf{k} = \mathbf{p}_1 + \mathbf{p}_2$ and (relative momentum) $\mathbf{P} = (1-z)\mathbf{p}_1 - z\mathbf{p}_2$

$$z = p_1^+ / (p_1^+ + p_2^+) \text{ and } (1-z) = p_2^+ / (p_1^+ + p_2^+)$$

***S*-matrix for *in* contribution in the back-to-back limit:** upon renaming $\mathbf{z} \rightarrow \mathbf{b}$ (No limit required!!)

$$S_{\gamma_T \rightarrow q_1 q_2}^{\text{in}} = i \frac{e e_f g 2\pi \delta(p_1^+ + p_2^+ - q^+)}{[\mathbf{P}^2 + (1-z)^2 m^2]} (1-z)^2 \bar{u}(1) \frac{\gamma^+ \gamma^-}{2} \Gamma_T^{\text{in}} \int_{\mathbf{b}} e^{-i\mathbf{b} \cdot \mathbf{k}} \int_{z^+} t^{a_2} U_F(+\infty, z^+; \mathbf{b}) \Psi(z^+, \mathbf{b})$$

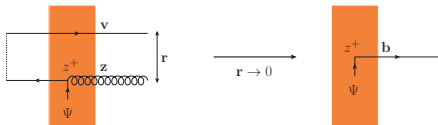

Back-to-back jets: *before* diagram

***S*-matrix for *bef* contribution in the back-to-back limit:**

define $\mathbf{b} = z\mathbf{v} + (1-z)\mathbf{z}$, $\mathbf{r} = \mathbf{z} - \mathbf{v}$

- phase: $e^{-i\mathbf{v}\cdot\mathbf{p}_1 - i\mathbf{z}\cdot\mathbf{p}_2 + i(\mathbf{v}-\mathbf{z})\cdot\mathbf{K}} \rightarrow e^{-i\mathbf{k}\cdot\mathbf{b} + i\mathbf{r}\cdot(\mathbf{P}-\mathbf{K})}$
- back-to-back limit: $\mathbf{P}^2 \gg \mathbf{k}^2 \Rightarrow \mathbf{r}^2 \ll \mathbf{b}^2$ (because of the phase factor), the color structure simplifies:

$$U_A(+\infty, z^+; \mathbf{z})_{a_2 b} U_F(\mathbf{v}) U_F^\dagger(z^+, -\infty; \mathbf{z}) t^b \Psi(z^+, \mathbf{z}) \rightarrow U_A(+\infty, z^+; \mathbf{b})_{a_2 b} U_F(\mathbf{b}) U_F^\dagger(z^+, -\infty; \mathbf{b}) t^b \Psi(z^+, \mathbf{b}) \\ = t^{a_2} U_F(+\infty, z^+; \mathbf{b}) \Psi(z^+, \mathbf{b})$$

$$S_{\gamma_{T,L} \rightarrow q_1 q_2}^{\text{bef}} \simeq i \frac{e e f g 2\pi \delta(p_1^+ + p_2^+ - q^+)}{[\mathbf{P}^2 + \bar{Q}^2]} \bar{u}(1) \frac{\gamma^+ \gamma^-}{2} \Gamma_{T,L}^{\text{bef}} \int_{\mathbf{b}} e^{-i\mathbf{b}\cdot\mathbf{k}} \int_{z^+} t^{a_2} U_F(+\infty, z^+; \mathbf{b}) \Psi(z^+, \mathbf{b})$$

Back-to-back qg dijet cross sections

In the back-to-back limit, the photon-target dijet cross section reads

$$(2\pi)^6 (2p_1^+) (2p_2^+) \frac{d\sigma^{\gamma T, L \rightarrow q_1 g_2}}{dp_1^+ d^2\mathbf{p}_1 dp_2^+ d^2\mathbf{p}_2} \Big|_{\text{corr.lim.}} = 2\pi\delta(p_1^+ + p_2^+ - q^+) (4\pi)^2 \alpha_{\text{em}} \alpha_s C_F e_f^2 \mathcal{H}_{T,L}(\mathbf{P}, z, Q) \mathcal{T}(\mathbf{k})$$

with the hard factors for the longitudinal and the transverse photon polarizations

$$\mathcal{H}_L = \frac{4Q^2 z^3 (1-z)^2}{[\mathbf{P}^2 + \bar{Q}^2]^2} \quad \bar{Q}^2 \equiv m^2 + z(1-z)Q^2$$

$$\mathcal{H}_T = z \left\{ \frac{(1+z^2)\mathbf{P}^2 + (1-z)^4 m^2}{[\mathbf{P}^2 + (1-z)^2 m^2]^2} + \frac{[z^2 + (1-z)^2]\mathbf{P}^2 + m^2}{[\mathbf{P}^2 + \bar{Q}^2]^2} - \frac{2z^2 \mathbf{P}^2}{[\mathbf{P}^2 + \bar{Q}^2][\mathbf{P}^2 + (1-z)^2 m^2]} \right\}$$

and the target averaged color operator

$$\mathcal{T}(\mathbf{k}) = \int_{\mathbf{b}, \mathbf{b}'} e^{-i\mathbf{k} \cdot (\mathbf{b} - \mathbf{b}')} \int_{z^+, z'^+} \left\langle \bar{\Psi}(z'^+, \mathbf{b}') \gamma^- U_F^\dagger(+\infty, z'^+; \mathbf{b}') U_F(+\infty, z^+; \mathbf{b}) \Psi(z^+, \mathbf{b}) \right\rangle$$

with a generalized CGC target average $\langle \dots \rangle$ over both the quark and gluon background fields.

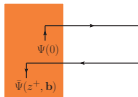

Not yet known how to explicitly perform this target average!

Recovering the unpolarized quark TMD

$$\mathcal{T}(\mathbf{k}) = \int_{\mathbf{b}, \mathbf{b}'} e^{-i\mathbf{k}\cdot(\mathbf{b}-\mathbf{b}')} \int_{z^+, z'^+} \langle \bar{\Psi}(z'^+, \mathbf{b}') \gamma^- U_F^\dagger(+\infty, z'^+; \mathbf{b}') U_F(+\infty, z^+; \mathbf{b}) \Psi(z^+, \mathbf{b}) \rangle$$

Can be related to the unpolarized quark TMD (with future staple gauge link):

$$f_1^q(x, \mathbf{k}) = \frac{1}{(2\pi)^3} \int_{\mathbf{b}} e^{i\mathbf{k}\cdot\mathbf{b}} \int_{z^+} e^{-iz^+ x P_{tar}^-} \langle P_{tar} | \bar{\Psi}(z^+, \mathbf{b}) \frac{\gamma^-}{2} U_F^\dagger(+\infty, z^+; \mathbf{b}) U_F(+\infty, 0; \mathbf{0}) \Psi(0, \mathbf{0}) | P_{tar} \rangle$$

Indeed, the CGC-like target average $\langle \dots \rangle$ is an effective model for the quantum expectation value in the target state $\langle P_{tar} | \dots | P_{tar} \rangle$, but with a normalization $\langle 1 \rangle = 1$.

\Rightarrow Both expectation values can be related as

$$\langle \mathcal{O} \rangle = \lim_{P'_{tar} \rightarrow P_{tar}} \frac{\langle P'_{tar} | \hat{\mathcal{O}} | P_{tar} \rangle}{\langle P'_{tar} | P_{tar} \rangle} = \lim_{P'_{tar} \rightarrow P_{tar}} \frac{\langle P'_{tar} | \hat{\mathcal{O}} | P_{tar} \rangle}{2P_{tar}^- (2\pi)^3 \delta(P'_{tar}^- - P_{tar}^-) \delta^{(2)}(\mathbf{P}'_{tar} - \mathbf{P}_{tar})}$$

With this relation, and after performing translations of the whole operator in $\mathcal{T}(\mathbf{k})$ in the + and transverse directions, one finds

$$\mathcal{T}(\mathbf{k}) = \frac{(2\pi)^3}{P_{tar}^-} f_1^q(x=0, \mathbf{k})$$

Factorized cross section with the quark TMD

Alternatively, in the correlation limit we can write the cross section in terms of \mathbf{k} , z and the dijet mass M_{jj}

$$M_{jj}^2 \equiv (p_1 + p_2)^2 = \frac{\mathbf{P}^2}{z(1-z)} + \frac{m^2}{z}$$

The cross section in the back-to-back limit in terms of the dijet mass:

$$\left. \frac{d\sigma^{\gamma_{T,L} \rightarrow q_1 q_2}}{dz dM_{jj}^2 d^2\mathbf{k}} \right|_{\text{corr.lim.}} = (2\pi) \frac{\alpha_{\text{em}} \alpha_s C_F e_f^2}{W^2} \tilde{\mathcal{H}}_{T,L}(M_{jj}, z, Q) f_1^q(x=0, \mathbf{k})$$

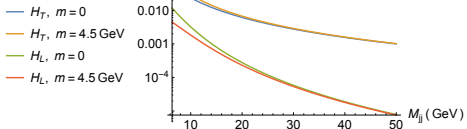

with the γ^* -target center of mass energy $W \simeq \sqrt{2q^+ P_{\text{tar}}^-}$ and the new hard factors

$$\tilde{\mathcal{H}}_L(M_{jj}, z, Q) = \frac{4Q^2 z(1-z)^2}{\left[(1-z)(M_{jj}^2 + Q^2) + m^2 \right]^2}$$

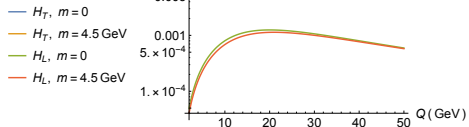

$$\begin{aligned} \tilde{\mathcal{H}}_T(M_{jj}, z, Q) &= \frac{(1+z^2)}{(1-z)} \frac{1}{\left[M_{jj}^2 - m^2 \right]} + \frac{(1-2z)}{\left[(1-z)(M_{jj}^2 + Q^2) + m^2 \right]} + \frac{(1-z) [2m^2 - (z^2 + (1-z)^2)Q^2]}{\left[(1-z)(M_{jj}^2 + Q^2) + m^2 \right]^2} \\ &\quad - \frac{2m^2}{\left[M_{jj}^2 - m^2 \right]^2} + \frac{2z(1-z)m^2}{\left[M_{jj}^2 - m^2 \right] \left[(1-z)(M_{jj}^2 + Q^2) + m^2 \right]} \end{aligned}$$

Behavior of the hard factors

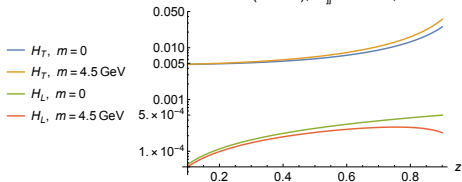

Hard factors (GeV^{-2}), $z=0.5$, $Q=5 \text{ GeV}$

Hard factors (GeV^{-2}), $M_{||}=20 \text{ GeV}$, $z=0.5$

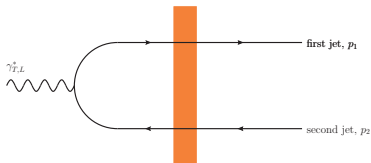

Hard factors (GeV^{-2}), $M_{||}=20 \text{ GeV}$, $Q=5 \text{ GeV}$

Background from eikonal $q\bar{q}$ dijet

First background process to qg dijet production:
(Eikonal) $q\bar{q}$ dijet production in DIS

Distinguishing these two processes depends on our ability to distinguish quark and gluon jets

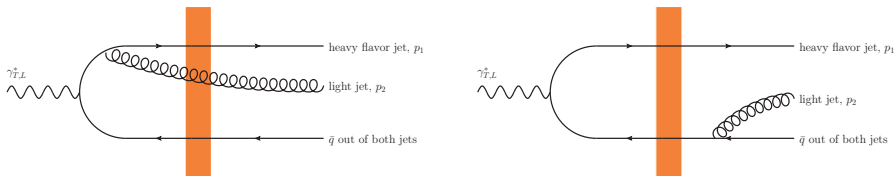

- Very challenging in general, for light quarks
- Heavy quark jets can be distinguished from light quark or gluon jets with heavy flavor tagging techniques

⇒ Focus on the heavy quark case to be able to separate qg dijets from $q\bar{q}$ dijets

Background from eikonal $q\bar{q}g$ production

Second background process to qg dijet production:

(Eikonal) $q\bar{q}g$ production in DIS, reconstructed as a qg dijet, and \bar{q} outside of both jets

Main difference with our qg process:

Emitted \bar{q} will take away some + momentum and some transverse momentum

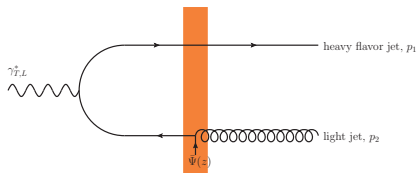

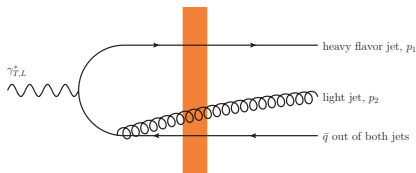

⇒ Background can be suppressed by imposing cuts on such momentum leaks :

- 1 Impose $(q^+ - p_1^+ - p_2^+) \ll q^+$
- 2 Impose $\mathbf{k}^2 \ll \mathbf{P}^2 = (1-z) \left[z M_{jj}^2 - m^2 \right]$ (back-to-back limit)

Applicability of the Eikonal approximation

Eikonal approximation: performed mostly at propagator level for each parton of the projectile, or radiated by the projectile.

→ Requires each of these partons to be far from the fragmentation region of the target

Ex: If final antiquark on the left diagram is close to the target fragmentation region, Eik approx not valid

→ Contribution to be accounted for by the diagram on the right instead!

Consistent high-energy expansion in powers

For generic kinematics of the jets, both types of contributions are potentially important and should be included (NEik with quark background fields, and Eik $q\bar{q}g$).

However, non-trivial interplay and risks of double counting!

⇒ Need to understand what are the precise kinematical restrictions to be applied to each unmeasured parton on the projectile side so that Eikonal approximation is valid.

Remark: It is a very general issue, relevant to other processes:

- SIDIS : needed to include both
 - Sea quarks from gluon splitting (Marquet, Xiao, Yuan, 2009)
 - Contribution from quark background (see talk by S. Mulani on friday)
- DIS : related issues in the **aligned jet** part of the phase space

Summary

- The quark background field of the target is relevant in CGC beyond the eikonal approximation
- We have calculated the qg dijet production in DIS in NEik CGC, driven by interaction with this quark background field
- TMD factorization of the cross section in the back-to-back limit: quark TMD (including valence) obtained from a (non-eikonal) CGC calculation!
- qg dijet in DIS: new way to probe the unpolarized quark TMD, in particular at the EIC
- This process can be distinguished from background processes at least in the heavy quark case, by required heavy flavor tagging on a single jet of the dijet, and using appropriate kinematical cuts.
- In general: need to build a consistent scheme to treat unmeasured parton in the Eikonal expansion, to obtain correct high-energy expansion of observables without double counting
