C. Constantinou First-order nucleon-to-quark phase transition: Thermodynamically-consiste

- The size of nucleons (uncertain as it may be) implies that deconfined quark matter can exist in the cores of NSs.
- ▶ However, such a possibility lacks observational and theoretical support:
  - Measurements of M, R, Λ cannot differentiate normal and hybrid stars.
  - LQCD and PQCD not applicable to NS conditions.
- Possible solution: identify an observable with strong dependence on composition.
- Enter g-modes!

A B b

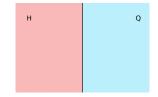

# Hybrid Matter: 1st Order Transitions

- ► Maxwell ("strong", "stiff", ...)
  - Infinite interface tension
  - No phase mixing
  - Local charge neutrality
  - $\triangleright \ \varepsilon = f(\varepsilon_H + \varepsilon_{eH}) + (1 f)(\varepsilon_Q + \varepsilon_{eQ})$
- ▶ Gibbs ("weak", "soft", ...)
  - Zero surface tension
  - Complete phase mixing
  - Global charge neutrality
  - $\triangleright \ \varepsilon = f \varepsilon_H + (1 f) \varepsilon_Q + \varepsilon_{eM}$

#### Intermediate case

- Some phase mixing
- Charge neutrality is partially local and partially global

$$\varepsilon = f(\varepsilon_H + \eta \varepsilon_{eH}) + (1 - f)(\varepsilon_Q + \eta \varepsilon_{eQ}) + (1 - \eta)\varepsilon_{eM}$$

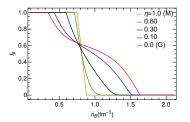

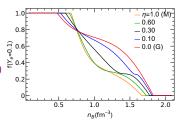

### Hybrid Matter: 1st Order Transitions (cont'd)

#### Constraints

- Baryon number conservation  $1 = f(y_n + y_p) + (1 - f)(y_u + y_d + y_s)/3$
- Lepton number conservation  $0 = y_e - f \eta y_{eH} - (1 - f) \eta y_{eQ} - (1 - \eta) y_{eM}$
- Local charge neutrality  $0 = (y_p - y_{eH}) = (2y_u - y_d - y_s)/3 - y_{eQ}$
- Global charge neutrality  $0 = fy_p + (1 - f)(2y_u - y_d - y_s)/3 - y_{eM}$

- **Equilibrium** (= minimization of  $\varepsilon$  wrt f,  $y_i$ ,  $\eta$ )
  - Mechanical,  $P_H + \eta P_{eH} = P_Q + \eta P_{eQ}$
  - Quark weak,  $\mu_d = \mu_s$
  - Neutral strong,  $\mu_n = \mu_u + 2\mu_d$
  - Charged strong,  $\mu_p = 2\mu_u + \mu_d \eta(\mu_{eH} \mu_{eQ})$
  - ► Beta  $\mu_d = \mu_u + \eta \mu_{eQ} + (1 \eta) \mu_{eM}$ -or-  $\mu_p = \mu_n - \eta \mu_{eH} - (1 - \eta) \mu_{eM}$
  - $\eta$  optimization,  $\varepsilon_{eM} = f \varepsilon_{eH} + (1 f) \varepsilon_{eQ}$

## Equation of State

Nucleons: Zhao - Lattimer

$$\epsilon_B = \sum_{h=n,p} \frac{1}{\pi^2} \int_0^{k_{Fh}} k^2 \sqrt{M_B^2 + k^2} \, dk + n_B V(u, v)$$

$$V = 4x(1-x)(a_0 u + b_0 u^{\gamma})$$

$$+ (1-2x)^2(a_1 u + b_1 u^{\gamma_1})$$

Quarks: vMIT

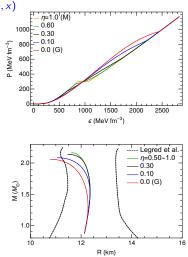

$$\mathcal{L} = \sum_{q=u,d,s} \left[ \bar{\psi}_q \left( i \partial - m_q - B \right) \psi_i + \mathcal{L}_{int} \right] \Theta$$

$$\mathcal{L}_{\text{int}} = -G_{v} \sum_{q} \psi \gamma_{\mu} V^{\mu} \psi + (m_{V}^{2}/2) V_{\mu} V^{\mu}$$
$$\epsilon_{Q} = \sum_{v} \epsilon_{\text{FG},q} + \frac{1}{2} \left(\frac{G_{v}}{2}\right)^{2} n_{Q}^{2} + B$$

$$\epsilon_Q = \sum_q \epsilon_{\rm FG,q} + \frac{1}{2} \left( \frac{1}{m_V} \right) n_Q + D$$

Leptons: noninteracting, relativistic fermions

$$\epsilon_L = \sum_{l=e,\mu} \frac{1}{\pi^2} \int_0^{k_{Fh}} k^2 \sqrt{m_L^2 + k^2} \, dk$$

- Global, long-lived, nonradial fluid oscillations resulting from fluid-element perturbations in a stratified environment.
- ▶ Slow chemical equilibration generates buoyancy forces to oppose dispacement.
- ▶ In stably-stratified systems the opposing force sets up oscillations with a characteristic frequency [Brunt-Väisälä,  $N^2 = g^2 \Delta(c^{-2})e^{\nu-\lambda}$ ] which depends on both the equilibrium and the adiabatic sound speeds [ $\Delta(c^{-2}) = c_{eq}^{-2} c_{ad}^{-2}$ ].
  - $\blacktriangleright c_{\rm eq}^2(n_B) = \frac{dP}{d\varepsilon} = \frac{dP_{\beta}}{dn_{\rm B}} \left(\frac{d\varepsilon_{\beta}}{dn_{\rm B}}\right)^{-1}$

mechanical equilibrium restored instantaneously.

- $\begin{array}{l} \blacktriangleright \ c_{\rm ad}^2(n_{\rm B},x) = \left(\frac{\partial P}{\partial \varepsilon}\right)_x = \left.\frac{\partial P}{\partial n_{\rm B}}\right|_x \left(\left.\frac{\partial \varepsilon}{\partial n_{\rm B}}\right|_x\right)^{-1} \\ c_{\rm ad,\beta}^2(n_{\rm B}) = c_{\rm ad}^2[n_{\rm B},x_\beta(n_{\rm B})] \\ \text{slow restoration of chemical equilibrium because } \tau_\beta \gg \tau_{\rm oscillation}. \end{array}$
- g-mode oscillations couple to tidal forces; they can be excited in a NS merger and provide information on the interior composition.
- Detection remains a challenge; but within sensitivity of 3rd generation detectors.

ロトス得トスラトスラト

# g-mode Signals

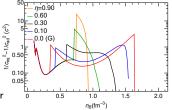

•  $\Delta(c^{-2}) = c_{eq}^{-2} - c_{ad}^{-2}$  drives the restoring force for g-mode oscillations. In *npe* matter,

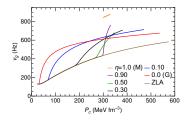

$$c_{\rm ad}^2 = c_{\rm eq}^2 + \left[ n_B \left( \frac{\partial \tilde{\mu}}{\partial n_B} \right)_x \right]^2 \left[ \mu_n \left( \frac{\partial \tilde{\mu}}{\partial x} \right)_{n_B} \right]^{-1}$$
$$\tilde{\mu} = \mu_e + \mu_p - \mu_n \stackrel{\beta - \rm eq.}{\longrightarrow} 0$$

- Dramatic changes in v<sub>g</sub> require new DOFs not just a smooth change in composition.

#### Discontinuity g-modes

- Generated by the flatness of P(n<sub>B</sub>) in a Maxwell mixed phase that leads to a density jump in the core of a hybrid star.
- Characterized by discontinuous g-mode frequencies.
- A special case of a compositional g-mode in the limit  $\eta \rightarrow 1$ .

## Summary

- Construction of a thermodynamically-consistent framework for the treatment of 1st-order phase transitions intermediate to Maxwell and Gibbs.
- Beware of the Maxwell construction!
- Calculation of g-mode properties for 1st-order phase transitions and for crossovers.
- g-modes can detect nonnucleonic matter in the cores of NS; assuming quark matter (by some other means), g-modes can distinguish between a first-order phase transition and a crossover.
- Discontinuity g-modes as a special case of compositional g-modes in the Maxwell limit.
- ► (Near) Future:
  - Extend 1st-order phase transition scheme to finite *T*.
  - Applications to protoneutron stars (cooling, superfluidity) and binary mergers.
  - Construct EOS that uses the same underlying description for quarks and hadrons.
