- **Why are  $\gamma_v$  NN\* electrocouplings interesting?** Probing bound valence quarks, baryon wave functions, the emergence of mass, and finally strong QCD.
- **What is needed beyond CLAS12?** Beam energy and a high acceptance (exclusive), and high-luminosity detector (beam time) with good  $W$  resolution.

---

# Why is it Interesting?

# Emergence of Hadron Mass Traced by Electromagnetic Probes

● QUARKS ● LEPTONS ● BOSONS ● HIGGS BOSON

$$\mathcal{L} = \frac{1}{4g^2} G_{\mu\nu}^a G_{\mu\nu}^a + \sum_j \bar{q}_j (i \not{\partial} D_\mu + m_j) q_j$$

where  $G_{\mu\nu}^a \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + if_{bc}^a A_\mu^b A_\nu^c$

and  $D_\mu \equiv \partial_\mu + it^a A_\mu^a$

That's it!

## Nucleon Resonance Electroexcitation Amplitudes and Emergent Hadron Mass

Daniel S. Carman<sup>1,†</sup>, Ralf W. Gothe<sup>2,†</sup>, Victor I. Mokeev<sup>1,†</sup>, and Craig D. Roberts<sup>3,4,†</sup>\*

**Abstract:** Understanding the strong interaction dynamics that govern the emergence of hadron mass (EHM) represents a challenging open problem in the Standard Model. In this paper we describe new opportunities for gaining insight into EHM from results on nucleon resonance ( $N^*$ ) electroexcitation amplitudes (*i.e.*  $\gamma_v p N^*$  electrocouplings) in the mass range up to 1.8 GeV for virtual photon four-momentum squared (*i.e.* photon virtualities  $Q^2$ ) up to  $7.5 \text{ GeV}^2$  available from exclusive meson electroproduction data acquired during the 6-GeV era of experiments at Jefferson Laboratory (JLab). These results, combined with achievements in the use of continuum Schwinger function methods (CSMs), offer new opportunities for charting the momentum dependence of the dressed quark mass from results on the  $Q^2$ -evolution of the  $\gamma_v p N^*$  electrocouplings. This mass function is one of the three pillars of EHM and its behavior expresses influences of the other two, *viz.* the running gluon mass and momentum-dependent effective charge. A successful description of the  $\Delta(1232)3/2^+$  and  $N(1440)1/2^+$  electrocouplings has been achieved using CSMs with, in both cases, common momentum-dependent mass functions for the dressed quarks, for the gluons, and the same momentum-dependent strong coupling. The properties of these functions have been inferred from nonperturbative studies of QCD and confirmed, *e.g.*, in the description of nucleon and pion elastic electromagnetic form factors. Parameter-free CSM predictions for the electrocouplings of the  $\Delta(1600)3/2^+$  became available in 2019. The experimental results obtained in the first half of 2022 have confirmed the CSM predictions. We also discuss prospects for these studies during the 12-GeV era at JLab using the CLAS12 detector, with experiments that are currently in progress, and canvass the physics motivation for continued studies in this area with a possible increase of the JLab electron beam energy up to 22 GeV. Such an upgrade would finally enable mapping of the dressed quark mass over the full range of distances (*i.e.* quark momenta) where the dominant part of hadron mass and  $N^*$  structure emerge in the transition from the strongly coupled to perturbative QCD regimes.

## 6.5 Bound Three-Quark Structure of Excited Nucleons and Emergence of Hadron Mass

D.S. Carman, R.W. Gothe, V.I. Mokeev, C.D. Roberts

### 6.5.1 The Emergent Hadron Mass Paradigm

The Standard Model of Particle Physics has one well-known mass-generating mechanism for the most elementary constituents of Nature, *viz.* the Higgs boson [295, 296], which is critical to the evolution of the Universe. Yet, alone, the Higgs is responsible for just 1% of the visible mass in the Universe. Visible matter is constituted from nuclei found on Earth and the mass of each such nucleus is largely the sum of the masses of the nucleons they contain. However, only 9 MeV of a nucleon's mass,  $m_N = 940$  MeV, is directly generated by Higgs boson couplings into quantum chromodynamics (QCD). Evidently, as highlighted by Fig. 46, Nature has another, very effective, mass-generating mechanism. Often called emergent hadron mass (EHM) [202, 297–299], it is responsible for 94% of  $m_N$ , with the remaining 5% generated by constructive interference between EHM and the Higgs boson. This makes studies of the structure of ground and excited nucleon states in experiments with electromagnetic probes a most promising avenue to gain insight into the strong interaction dynamics that underlie the emergence of the dominant part of the visible mass in the Universe [105, 202, 300–302].

Figure 46: Proton mass budget, drawn using a Poincaré-invariant decomposition: emergent hadron mass (EHM) = 94%; Higgs boson (HB) contribution = 1%; and EHM+HB interference = 5%. (Separation at renormalization scale  $\zeta = 2$  GeV, calculated using information from Refs. [22, 303–305]).
