Introduction & motivation

Introduction & motivation

Strangeness physics

- ▶ Interdisciplinary field connecting particle physics, nuclear physics, and astrophysics
- ▶ One of its major goals is to understand the elusive interaction of hyperons with nucleons and the nuclear medium

Theoretical analysis of hypernuclei

- ▶ Using **'effective'** YN interaction models & mean-field / shell-model approaches – successful but difficult to link with the underlying free-space YN interaction, limited predictive power
- ▶ Using **'realistic'** (free-space) YN interaction models ...

Constraining YN interactions

- ▶ **YN scattering** – 'pure' but very difficult to realize, sparse database with large uncertainties (J-PARC)
- ▶ Heavy-ion collisions – **production and decays** of light hypernuclei, correlation **femtoscopia** (HADES, ALICE, STAR)
- ▶ **Final-state interactions** in hyperon photoproduction (CLAS)
- ▶ **Lattice QCD** (HAL QCD, NPLQCD)
- ▶ **Hypernuclei** – precise spectroscopy of hypernuclear energy levels

Introduction & motivation

Theoretical analysis of hypernuclei using realistic YN interactions

- ▶ Combines modern developments of YN interactions based on χ EFT and ab initio few- and many-body approaches
- ▶ Computationally demanding
- ▶ Can reveal deficiencies of existing YN interaction models \rightarrow calibration?

Calibration of YN interaction models using hypernuclei requires

- ▶ Advanced 'ab initio' **computational methods**
- ▶ Quantified **method uncertainties**, σ_{method} – associated with the solution of the many-body problem
- ▶ Quantified **model uncertainties**, σ_{model} – associated with the choice of the nuclear interaction
- ▶ Overcoming the **computational demands** – large number of evaluations
- ▶ Sensitivity analysis - hypernuclear spectra **might not be sensitive** to certain parameters (LECs) of the YN interaction models
- ▶ **Simultaneous** fitting of other observables

Ab initio calculations of light hypernuclei

Ab initio calculations of light hypernuclei

- ▶ Ab initio methods aim to solve the (hyper)nuclear many-body problem starting from realistic (free-space) interactions exactly or with **controlled approximations**

Ab initio no-core shell model

- ▶ Quasi-exact method to solve the few- and many-body Schrödinger equation

$$\left(\sum \frac{\hat{\mathbf{p}}_i^2}{2m_i} + \sum \hat{V}_{\text{NN};ij} + \sum \hat{V}_{\text{NNN};ijk} + \sum \hat{V}_{\text{YN};ij} \right) \Psi = E\Psi$$

[Navrátil et al., JPG 36, 083101 (2009); DG et al., FBS 55, 857 (2014); Wirth et al., PRL 113, 192502 (2014);
Le et al., EPJA 56, 301 (2020)]

- ▶ Wave function is expanded and Hamiltonian is diagonalized in a finite A-particle harmonic oscillator (HO) basis

$$\Psi(\mathbf{r}_1, \dots, \mathbf{r}_A) = \sum_{N \leq N_{\text{max}}} \Phi_{N,\omega}^{\text{HO}}(\mathbf{r}_1, \dots, \mathbf{r}_A)$$

Converges to exact results for $N_{\text{max}} \rightarrow \infty$

- ▶ Input NN+NNN and YN interactions derived from χ EFT
 - ▶ The NNLO_{sim} family at NNLO [Carlsson et al., PRX 6, 011019 (2016)]
 - ▶ Jülich YN at LO [Polinder et al., NPA 779, 244 (2006)]

Ab initio calculations of light hypernuclei: method uncertainties

- ▶ Method uncertainties associated with convergence of the solution of the many-body problem

- ▶ NCSM-calculated energies typically exhibit undesired dependence on the HO basis frequency $\hbar\omega$ and truncation N_{\max}
- ▶ Convergence properties of observables calculated in finite HO bases are rather well understood [Wendt et al., PRC 91, 061391 (2015)]
 - ▶ NCSM model-space parameters ($N_{\max}, \hbar\omega$) recast into infrared (IR) and ultraviolet (UV) scales ($L_{\text{IR}}, \Lambda_{\text{UV}}$)
 - ▶ In a regime with negligible UV corrections, IR corrections are universal

$$E(L_{\text{IR}}) = E_{\infty} + a_0 \exp(-2\kappa_{\infty} L_{\text{IR}}) + \dots$$

Ab initio calculations of light hypernuclei: method uncertainties

- Infrared extrapolation formulated as a Bayesian inference problem

$$E(L_{\text{IR}}) = E_{\infty} + \Delta E_{\text{IR}} \exp(-2\kappa_{\infty} \Delta L_{\text{IR}}) \times \left(1 + \frac{\epsilon_{\text{NLO}}}{\kappa_{\infty}(L_{\text{IR}, \text{max}} + \Delta L_{\text{IR}})} \right),$$

with data $\mathcal{D} = \{E(L_{\text{IR},i})\}$ calculated in different model spaces and $\vec{\epsilon}_{\text{NLO}} \sim \mathcal{N}(0, \Sigma(\bar{\epsilon}, \rho))$ providing a stochastic model for the NLO energy correction

- Method uncertainty quantified by **68 % credible interval** for the extrapolated energy E_{∞}

	B_{Λ}^{Exp} (MeV)	B_{Λ}^{th} (MeV)	
		median	68 % $\text{CI}_{\text{method}}$
${}^3_{\Lambda}\text{H}$	0.164(43)	0.166	$[-0.001, +0.001]$
${}^4_{\Lambda}\text{H}$	2.157(77)	2.78	$[-0.01, +0.01]$
${}^4_{\Lambda}\text{He}$	2.39(3)	2.76	$[-0.01, +0.01]$
${}^5_{\Lambda}\text{He}$	3.12(2)	6.03	$[-0.28, +0.18]$
${}^4_{\Lambda}\text{H}; 1^+$	1.067(80)	1.75	$[-0.12, +0.10]$
${}^4_{\Lambda}\text{He}; 1^+$	0.984(50)	1.71	$[-0.13, +0.10]$

[DG, Htun, Forssén, PRC 106, 054001 (2022)]

- Validation for ${}^3_{\Lambda}\text{H}$

Ab initio calculations of light hypernuclei: model uncertainties

- ▶ Dominating source of uncertainty of hypernuclear observables likely comes from the underlying YN interaction $\leftarrow \chi$ EFT truncation, regulator artifacts, calibration data uncertainties
- ▶ Energy levels of light hypernuclei are also sensitive to details of the employed **nuclear NN+NNN interactions**
- ▶ One can naively expect that calculated Λ separation energies should be insensitive to the choice of nuclear interaction, $B_\Lambda = E(^A Z) - E(^A_\Lambda Z)$
- ▶ A rather weak residual dependence of B_Λ was found using a **limited set** of phenomenological [Nogga et al., PRL 88, 172501 (2002)] and χ EFT [Le et al., EPJA 56, 301 (2020)] NN interactions

Ab initio calculations of light hypernuclei: model uncertainties

- ▶ To expose the magnitude of systematic model uncertainties in B_Λ we employed [DG, Htun, Forssén, PRC 106, 054001 (2022)] the NNLO_{sim} family of 42 different nuclear NN+NNN interactions [Carlsson et al., PRX 6, 011019 (2016)]

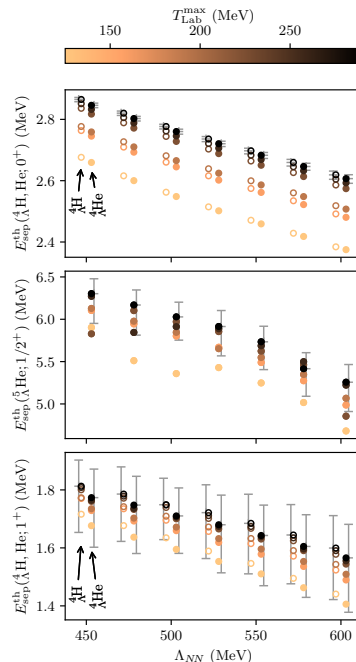

- ▶ NNLO_{sim} LECs fitted to reproduce simultaneously π N, NN, and NNN low-energy observables
- ▶ Experimental data uncertainties propagate into the LECs

- ▶ Model uncertainty connected to the choice of nuclear Hamiltonian quantified by variance, $\sigma^2(\text{NNLO}_{\text{sim}})$, of predictions for B_Λ

- ▶ For LO YN:

	${}^3_\Lambda\text{H}$	${}^4_\Lambda\text{H}$	${}^4_\Lambda\text{He}$	${}^4_\Lambda\text{H}_{1^+}$	${}^4_\Lambda\text{He}_{1^+}$	${}^5_\Lambda\text{He}$
σ_{model} (keV)	20	80	80	70	70	360

- ▶ A smaller NN+NNN-model dependence was found for NLO and NNLO YN interactions [Le et al., EPJA 60, 3 (2024)]

Ab initio calculations of hypernuclei: the curse of dimensionality

- ▶ Ab initio methods provide a reliable link between the properties of hypernuclei and the underlying hyperon–nucleon interactions
- ▶ Is it possible to directly incorporate them in **optimization of hyperon–nucleon forces** which require a large number of model evaluations?

- ▶ This is not feasible given their computational cost
- ▶ Reoptimization of 2 LECs to the p-shell hypernuclei Λ separation energies [Knoll, Roth, PLB 846, 138258 (2023)]

**Emulating ab initio NCSM
calculations: eigenvector
continuation**

Emulating ab initio NCSM calculations: eigenvector continuation

- ▶ Eigenvector continuation is based on the fact that when a Hamiltonian depends smoothly on some real-valued control parameter(s), any eigenvector is a smooth function of that parameter(s) and its trajectory is confined to a very low-dimensional subspace

[Frame et al., PRL 121, 032501 (2018); König et al., PLB 810, 135814 (2020)]

Parameter domain

- ▶ Write the Hamiltonian in a **linearized** form

$$H(\vec{c}) = H_0 + \sum c_i H_i$$

- ▶ Select ‘training’ points $\{\vec{c}_i\}$ and solve the exact problem $H(\vec{c}_i) |\psi_i\rangle = E_i |\psi_i\rangle$

- ▶ **Project the Hamiltonian onto the subspace of training eigenvectors** $\{|\psi_i\rangle\}$ and diagonalize the generalized eigenvalue problem

$$\tilde{H}(\vec{c}_+) |\tilde{\psi}\rangle = \tilde{E}_+ \tilde{N} |\tilde{\psi}\rangle,$$

where $\tilde{H}_{ij} = \langle \psi_i | H(\vec{c}_+) | \psi_j \rangle$, $\tilde{N}_{ij} = \langle \psi_i | \psi_j \rangle$ and \tilde{E}_+ approximates E_+

Emulating ab initio NCSM calculations: eigenvector continuation

- ▶ Hypernuclear Hamiltonian with LO YN interactions can be linearized,

$$H = H_0 + C_{27}V_{27} + C_{10^*}V_{10^*} + C_{10}V_{10} + C_{8a}V_{8a} + C_{8s}V_{8s},$$

where C_i s are the 5 independent $SU_f(3)$ LECs and H_0 contains the kinetic energy, NN+NNN interactions, and hypernuclear meson-exchange and Coulomb interactions

- ▶ ${}^5_{\Lambda}\text{He}; \frac{1}{2}^+$, model space truncation $N_{\max} = 12$
 - ▶ Vary one LEC, C_{27} , within $\pm 100\%$ relative variation with respect to the nominal LOYN ($\Lambda_{\text{YN}} = 600$ MeV) value
 - ▶ Select **1, 2, 4** exact NCSM eigenvectors to construct the emulators
- ▶ **Accurate and lightning-fast** emulation of ab initio NCSM calculations
 - ▶ Continued eigenvectors stay within the same ($N_{\max}, \hbar\omega$) model space \rightarrow extrapolation of observables to infinite model space is still necessary

Emulating ab initio NCSM calculations: cross validation

- ▶ Select 2, 4, 8, 16, 32 points in the 5-dimensional space of LOYN LECs using the Latin hypercube space-filling design in a $\pm 20\%$ domain around the nominal values to train the emulators
- ▶ Select randomly 256 exact NCSM calculations within the same domain of LECs

- ▶ We can achieve relative accuracy of $|\delta_{\text{rel}}| < 1, 0.1, 0.002\%$ using 8, 16, 32 training points

Emulating ab initio NCSM calculations: cross validation

- ▶ Select 2, 4, 8, 16, 32 points in the 5-dimensional space of LOYN LECs using the Latin hypercube space-filling design in a $\pm 20\%$ domain around the nominal values to train the emulators
- ▶ Select randomly 256 exact NCSM calculations within the same domain of LECs

- ▶ We can achieve relative accuracy of $|\delta_{\text{rel}}| < 1, 0.1, 0.002\%$ using 8, 16, 32 training points

**Application: global sensitivity
analysis of hypernuclear spectra**

Application: global sensitivity analysis of hypernuclear spectra

Global sensitivity analysis

- ▶ Addresses the question of how variance of the output of a model can be apportioned to variances of the model inputs [Saltelli et al., CPC 181, 259 (2010)]
- ▶ Allows to **identify the most influential LECs** of χ EFT YN interactions which determine the hypernuclear **energy spectra**

- ▶ For an output $Y = f(\vec{\alpha})$ of a model f , we decompose the total variance as

$$\text{Var}[Y] = \sum_{i=1}^d V_i + \sum_{i < j=1}^d V_{ij} + \dots,$$

where

$$V_i = \text{Var}[E_{\vec{\alpha} \sim (\alpha_i)}[Y|\alpha_i]],$$

$$V_{ij} = \text{Var}[E_{\vec{\alpha} \sim (\alpha_i, \alpha_j)}[Y|\alpha_i, \alpha_j]] - V_i - V_j,$$

are variances of conditional expectation of Y

- ▶ The variance integrals are computed by using quasi-MC sampling, including 95 % confidence intervals
- ▶ The first-, second-, and higher-order (Sobol') **sensitivity indices**

$$S_i = \frac{V_i}{\text{Var}[Y]}, \quad S_{ij} = \frac{V_{ij}}{\text{Var}[Y]}, \quad \dots$$

- ▶ Total effect

$$S_{Ti} = S_i + S_{ij} + \dots$$

Application: global sensitivity analysis of hypernuclear spectra

- Identify the most influential LECs:

$Y = \Lambda$ separation energies of ${}^3_{\Lambda}H_{\frac{1}{2}^+}$, ${}^4_{\Lambda}H_{0^+}$, ${}^4_{\Lambda}He_{0^+}$, ${}^4_{\Lambda}H_{1^+}$, ${}^4_{\Lambda}He_{1^+}$, ${}^5_{\Lambda}He_{\frac{1}{2}^+}$,

$\vec{\alpha} =$ the 5 LECs of the LOYN interaction; independent and uniformly distributed within $\pm 2\%$ ($\pm 20\%$) variation around the nominal values of LOYN ($\Lambda_{YN}=600$ MeV) for ${}^3_{\Lambda}H$ ($A = 4, 5$)

- $S_i \approx S_{Ti} \rightarrow$ energies are additive in all LECs
- C_{27} is responsible for most of the variation in energy

$$C_{1S_0}^{\Lambda} = \frac{1}{10}(9C_{27} + C_{8s})$$

$$C_{3S_1}^{\Lambda} = \frac{1}{2}(C_{10^*} + C_{8a})$$

$$C_{3S_1}^{\Sigma} = C_{10}$$

Application: global sensitivity analysis of hypernuclear spectra

- Identify the most influential LECs:

$Y = \Lambda$ separation energies of ${}^3_{\Lambda}H_{\frac{1}{2}^+}$, ${}^4_{\Lambda}H_{0^+}$, ${}^4_{\Lambda}He_{0^+}$, ${}^4_{\Lambda}H_{1^+}$, ${}^4_{\Lambda}He_{1^+}$, ${}^5_{\Lambda}He_{\frac{1}{2}^+}$,

$\vec{\alpha} =$ the 5 LECs of the LOYN interaction; independent and uniformly distributed within $\pm 2\%$ ($\pm 20\%$) variation around the nominal values of LOYN ($\Lambda_{YN}=600$ MeV) for ${}^3_{\Lambda}H$ ($A = 4, 5$)

- $S_i \approx S_{Ti} \rightarrow$ energies are additive in all LECs

Summary & outlook

Summary & outlook

Ab initio calculations of light hypernuclei

- ▶ Hypernuclear observables, such as **Λ separation energies** in light hypernuclei, suffer from **sizable theoretical uncertainties** associated with the choice of nuclear interaction (with LO χ EFT YN interaction)

Emulating ab initio NCSM

- ▶ **Eigenvector continuation** provides **fast and accurate** emulation of ab initio calculations of light hypernuclei
- ▶ Global sensitivity analysis identifies **the most influential LECs** of χ EFT YN interactions which **determine the energy spectra** of light hypernuclei
- ▶ A **significantly better description** of energy levels of light hypernuclei can be achieved with a relatively small variation of the LECs

Outlook

- ▶ **Simultaneous optimization** of YN interactions using bound-state and scattering observables with accompanying **uncertainty quantification**

Thank you!
