

Recent progress on the QCD phase diagram

More precision in a smaller volume

Jana N. Guenther

September 12th 2024

Motivation for a small volume

- It saves computational time:
 - fewer lattice points
 - less noise on derivatives
 - often reduces overlap problem in reweighting methods
- Investigation of transitions requires finite volume scan
- Heavy ion collisions take place in a finite volume (though it is not clear, how to translate to the lattice)
- Point of interest for DSE ([Bernhardt:2022mnx], [Bernhardt:2021iq])

Fluctuations on the lattice

$$\chi_{i,j,k}^{B,Q,S} = \frac{\partial^{i+j+k}(p/T^4)}{(\partial\hat{\mu}_B)^i(\partial\hat{\mu}_Q)^j(\partial\hat{\mu}_S)^k}, \quad \hat{\mu}_i = \frac{\mu}{T}$$

Today:

$$\chi_i^B = \frac{\partial^i(p/T^4)}{(\partial\hat{\mu}_B)^i}$$

Lattice set-up

- 4Hex + dbw2 action
- lattices: $16^3 \times 8$, $20^3 \times 10$, $24^3 \times 12$
- $\mu_S = 0$
- scale setting with f_π and w_1
- Exponential definition of the chemical potential (introduced like a constant imaginary gauge field) \rightarrow derivatives with respect to the chemical potential can be shown to be UV finite by virtue of a $U(1)$ symmetry [Hasenfratz:1983ba]

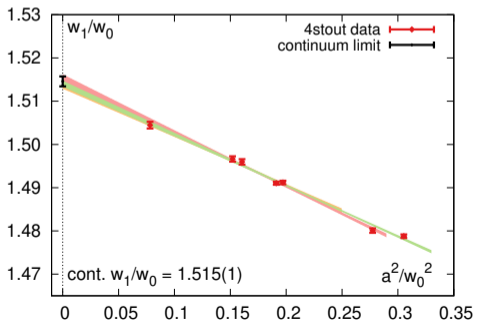

Systematic errors

We have to deal with systematic errors from the continuum extrapolation and the scale setting.

Systematic errors

We have to deal with systematic errors from the continuum extrapolation and the scale setting. Scale setting is done with f_π and w_1 .

$$W(t)|_{t=w_1^2} = 0.7, \quad W(t) \equiv t \frac{d}{dt} \{ t^2 \langle E(t) \rangle \}$$

Systematic errors

We have to deal with systematic errors from the continuum extrapolation and the scale setting. Scale setting is done with f_π and w_1 .

$$W(t)|_{t=w_1^2} = 0.7, \quad W(t) \equiv t \frac{d}{dt} \{t^2 \langle E(t) \rangle\}$$

Continuum extrapolation:

$$\hat{O}(T, 1/N_\tau^2) = \sum_{i=1}^M \left(\alpha_i + \beta_i \frac{1}{N_\tau^2} \right) s_i(T),$$

s_i : set of basis spline function. We take three different sets of node points.

Systematic errors

We have to deal with systematic errors from the continuum extrapolation and the scale setting. Scale setting is done with f_π and w_1 .

$$W(t)|_{t=w_1^2} = 0.7, \quad W(t) \equiv t \frac{d}{dt} \{t^2 \langle E(t) \rangle\}$$

Continuum extrapolation:

$$\hat{O}(T, 1/N_\tau^2) = \sum_{i=1}^M \left(\alpha_i + \beta_i \frac{1}{N_\tau^2} \right) s_i(T),$$

s_i : set of basis spline function. We take three different sets of node points.

The final results are obtained by combining the $6 = 2 \times 3$ analyses to construct a histogram.

Conclusion

- First continuum extrapolated results for high order baryon number fluctuations
- A 4Hex + dbw2 action allowed for a continuum limit from $N_t = 8, 10, 12$
- With $LT = 2$ the volume effects are under control in the low temperature region.

What we work with

- To access zeros of Z , we can look at $\log(Z) = p$
- Written as a Taylor series

$$\Delta p = \frac{p(T, \mu_B) - p(T, 0)}{T^4} = \sum_{n=0} \frac{\chi_{2n}(T)}{(2n)!} \left(\frac{\mu_B}{T}\right)^{2n} \quad \chi_n = \frac{\partial^n (p/T^4)}{(\partial \mu/T)^2}$$

- χ_{2n} is given by simulations at $\mu_B = 0$
- These coefficients can be used in conjunction with a scaling relation for extrapolation
- In addition we can model:

$$\chi_1(T, \mu_B) = \sum_{n=1} \frac{\chi_{2n}(T)}{(2n-1)!} \left(\frac{\mu_B}{T}\right)^{2n+1} \quad \chi_2(T, \mu_B) = \sum_{n=0} \frac{\chi_{2n+2}(T)}{(2n)!} \left(\frac{\mu_B}{T}\right)^{2n}$$

Lee-Yang zeros and padé approximations

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

- Convert by solving algebraically: $P_m(x) = T_l(x)(1 + Q_n(x))$ with $T_l(x) = \sum_{i=0}^l c_i x^i$

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

- Convert by solving algebraically: $P_m(x) = T_l(x)(1 + Q_n(x))$ with $T_l(x) = \sum_{i=0}^l c_i x^i$
- solving the equation $1 + Q_n(x) \stackrel{!}{=} 0$ gives the Poles

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

- Convert by solving algebraically: $P_m(x) = T_l(x)(1 + Q_n(x))$ with $T_l(x) = \sum_{i=0}^l c_i x^i$
- solving the equation $1 + Q_n(x) \stackrel{!}{=} 0$ gives the Poles
- Example using $1/\cosh(z)$

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

- Convert by solving algebraically: $P_m(x) = T_l(x)(1 + Q_n(x))$ with $T_l(x) = \sum_{i=0}^l c_i x^i$
- solving the equation $1 + Q_n(x) \stackrel{!}{=} 0$ gives the Poles
- Example using $1/\cosh(z)$

$$\text{Pade}[m, n] : \frac{P_m(x)}{1+Q_n(x)} = \frac{\sum_{i=0}^m a_i x^i}{1+\sum_{i=1}^n b_i x^i}$$

- Convert by solving algebraically: $P_m(x) = T_l(x)(1 + Q_n(x))$ with $T_l(x) = \sum_{i=0}^l c_i x^i$
- solving the equation $1 + Q_n(x) \stackrel{!}{=} 0$ gives the Poles
- Example using $1/\cosh(z)$

Padé with Noise

- Adding 3% of noise to each of the derivatives of $1/\cosh(z)$:

 - Results
- 2 Criticality from fluctuations
 - Lee-Yang zeros and Padé approximations
 - Results
- 3 Observables tailored to small volume [Borsanyi:2024dro]

Lattice Setup

- Volume : $16^3 \times 8$
- $\mathcal{O}(5 \cdot 10^5)$ configurations per T
- 4 HEX smearing
- Simulated at physical quark mass

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

- Poles:

$$1 + b_1\mu^2 + b_2\mu^4 \stackrel{!}{=} 0$$

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

- Poles:

$$1 + b_1\mu^2 + b_2\mu^4 \stackrel{!}{=} 0$$

- Repeat for each jackknife sample and independently for each temperature.

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

- Poles:

$$1 + b_1\mu^2 + b_2\mu^4 \stackrel{!}{=} 0$$

- Repeat for each jackknife sample and independently for each temperature.

modeling χ_2

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

- Poles:

$$1 + b_1\mu^2 + b_2\mu^4 \stackrel{!}{=} 0$$

- Repeat for each jackknife sample and independently for each temperature.
- Extrapolate T_c , via eg.
 $\text{Im}[\mu_B] = \kappa (\Delta T)^{\beta\delta}$

modeling χ_2

Analysis:

- $\chi_2, \chi_4, \chi_6, \chi_8 \implies [1, 2]$ -Padé in μ^2

$$f(T) = \frac{a_1 + a_2\mu^2}{1 + b_1\mu^2 + b_2\mu^4}$$

- Poles:

$$1 + b_1\mu^2 + b_2\mu^4 \stackrel{!}{=} 0$$

- Repeat for each jackknife sample and independently for each temperature.
- Extrapolate T_c , via eg.
 $\text{Im}[\mu_B] = \kappa (\Delta T)^{\beta\delta}$
- Estimate systematic effects
 - Use Δp or χ_1 or χ_2
 - Vary fit range in temperature
 - Use different scaling ansatz

modeling χ_2

Varying the approximated function

modeling χ_2 modeling $p - p_0$

Varying the scaling variable for χ_2 : $\kappa\Delta T = \text{Im}(x)^{1/\beta\delta}$

Varying the fit range for χ_2 

Combination

Based on $3 [\Delta p, \chi_1, \chi_2] \times 4 \left[\mu, \mu^2, \frac{\mu}{T}, \frac{\mu^2}{T^2} \right] \times 36$ Temp. ranges = 432 Fits

Conclusion

- We used a high statistics campaign to look for the Lang Yee Zeros
 - We can estimate T_c with a reasonable statistical error but a high systematic error
 - No systematic control of the Padé order
 - Approximation from a great distance requires strong assumptions
-
- Reliable prediction of the CEP with LYZ from the lattice data requires great care and consideration

Properties of QCD crossover

Chiral

- $SU(2) \times SU(2)$ symmetry in the limit $m_q \rightarrow 0$
- order parameter: chiral condensate $\langle \bar{\psi}\psi \rangle$
- we study the chiral condensate and its derivative the chiral susceptibility χ

Properties of QCD crossover

Chiral

- $SU(2) \times SU(2)$ symmetry in the limit $m_q \rightarrow 0$
- order parameter: chiral condensate $\langle \bar{\psi}\psi \rangle$
- we study the chiral condensate and its derivative the chiral susceptibility χ

Deconfinement

- Z_3 symmetry in the limit $m_q \rightarrow \infty$
- order parameter: Polykov loop
 $P \sim e^{-F_Q/T}$
- we study: derived from P the static quark free energy F_Q and the static quark entropy S_Q

Properties of QCD crossover

Chiral

- $SU(2) \times SU(2)$ symmetry in the limit $m_q \rightarrow 0$
- order parameter: chiral condensate $\langle \bar{\psi}\psi \rangle$
- we study the chiral condensate and its derivative the chiral susceptibility χ

We aim to investigate the volume dependence of T_c and the strength of the transition for $\mu_B > 0$ for different definitions

- $m_q \neq 0, \infty \rightarrow$ both only approximate order parameters
- Lattice \rightarrow true transitions do not happen in a finite volume
- how do **chiral** and **deconfinement** observables behave in the limit $LT \rightarrow \infty$

Deconfinement

- Z_3 symmetry in the limit $m_q \rightarrow \infty$
- order parameter: Polykov loop $P \sim e^{-F_Q/T}$
- we study: derived from P the static quark free energy F_Q and the static quark entropy S_Q

Lattice set-up

- tree-level Symanzik improved gauge action
- $N_f = 2 + 1 + 1$ staggered fermions with 4 stout smearing
- $N_t = 12$, $N_s = 20, 24, 28, 32, 40, 48, 64$
- For $N_s = 32, 40, 48$ simulations also at $\frac{\mu_B^J \pi}{8T} = 3, 4, 5, 6, 6.5, 7$
- strangeness neutrality setting $\langle n_S \rangle = 0$

Chiral observables

$$\langle \bar{\psi}\psi \rangle = \frac{T}{V} \frac{\partial \log Z}{\partial m_{ud}}$$

Chiral observables

$$\langle \bar{\psi}\psi \rangle = \frac{T}{V} \frac{\partial \log Z}{\partial m_{ud}}$$

Chiral observables

$$\langle \bar{\psi}\psi \rangle = \frac{T}{V} \frac{\partial \log Z}{\partial m_{ud}}$$

$$\chi = \frac{T}{V} \frac{\partial^2 \log Z}{\partial^2 m_{ud}}, \quad \chi^{\text{disc}} = \frac{T}{V} \frac{\partial^2 \log Z}{\partial m_u \partial m_d} \Big|_{m_u=m_d}$$

Chiral observables

$$\langle \bar{\psi}\psi \rangle = \frac{T}{V} \frac{\partial \log Z}{\partial m_{ud}}$$

$$\chi = \frac{T}{V} \frac{\partial^2 \log Z}{\partial^2 m_{ud}}, \quad \chi^{\text{disc}} = \frac{T}{V} \frac{\partial^2 \log Z}{\partial m_u \partial m_d} \Big|_{m_u=m_d}$$

T_c increases with the volume

Deconfinement observables

$$F_Q = -T \log \left(\frac{1}{V} |\langle \sum_{\vec{x}} P(\vec{x}) \rangle_T| \right)$$

Deconfinement observables

$$F_Q = -T \log \left(\frac{1}{V} \left| \langle \sum_{\vec{x}} P(\vec{x}) \rangle_T \right| \right)$$

$$S_Q = -\frac{\partial F_Q}{\partial T}$$

Deconfinement observables

$$F_Q = -T \log \left(\frac{1}{V} \left| \langle \sum_{\vec{x}} P(\vec{x}) \rangle_T \right| \right)$$

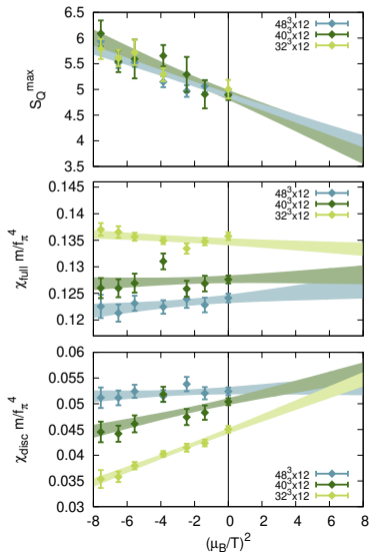

$$S_Q = -\frac{\partial F_Q}{\partial T}$$

Here volume effects are milder than for the [chiral](#) observables.

$\mu_B > 0$: Height of peaks of χ , χ_{disc} , S_Q

- A rise of the peak height, could indicate a strengthening of the transition
- This only happens for χ_{disc} , but seems to decrease with volume
- S_Q only has very mild volume effects

Conclusion

- In the thermodynamic limit $T_c^{(SQ)} < T_c^{(\chi_{\text{disc}})} < T_c^{(\chi)}$
- The volume dependence of T_c depends on the definition
- The **deconfinement** observables we investigated have a milder volume dependence than the **chiral** ones.
- Only the peak of χ_{disc} increases with μ_B

Summary
