Basic MagnetoHydroDynamics concepts

(good introduction:

H. C. Spruit 2013, "Essential magnetohydrodynamics for astrophysics")

Ideal MHD fluid is

- perfectly conducting $\rightarrow E = 0$ (in fluid rest frame)
- magnetized:

 $\nabla \cdot B = 0 \rightarrow {\rm field\ lines\ always\ close}$ Magnetic flux is conserved \rightarrow "flux freezing"

Flux freezing

Magnetic field lines are "transported along with the fluid"

[attribution: Chetvorno, CC0 license]

O. S. Salafia (INAF - INFN)

Jets in compact binary mergers

< □ ▶ < 🗇

Lorentz force

- $\bullet\,$ always perpendicular to ${\bf B}\,$
- towards negative mag. energy density gradient (\rightarrow equalize pressure)
- towards center of radius of curvature (\rightarrow straighten lines)

O. S. Salafia (INAF - INFN)

Magnetic pressure

O. S. Salafia (INAF - INFN)

Jets in compact binary mergers

2024-08-01

Force-free region

- $\mathbf{J} = \frac{1}{4\pi} (\nabla \times \mathbf{B}) \parallel \mathbf{B} \to \frac{\mathrm{d}\mathbf{F}}{\mathrm{d}V} = \frac{1}{4\pi} (\nabla \times \mathbf{B}) \times \mathbf{B} = 0$
- Needs high magnetization (other forces \ll Lorentz force)
- Minimum energy configuration (within the volume)
- Exterts stress on boundaries
Kerr black hole magnetosphere

[Price & Thorne 1988]

Blandford-Znajek luminosity

$$\begin{split} L_{\rm jet,\,BZ} \propto B_{\rm pol}^2 a_{\rm BH}^2 \\ \text{[Blandford \& Znajek '77, see also Tchekhovskoy et al. '12]} \\ \text{Taps BH rotational energy} \\ \sigma &= B^2/(4\pi\rho c^2) \text{ magnetization} \\ \rho \propto \dot{M} \\ \rightarrow B^2 \stackrel{\sim}{\propto} \dot{M} \\ \rightarrow L_{\rm jet,BZ} = \eta_{\rm BZ}(a_{\rm BH},...) \dot{M}c^2 \\ \text{But } \eta_{\rm BZ} \text{ can be } > 1 \end{split}$$

► 2024-08-01

< ∃ ►

▲□▶ ▲□▶ ▲ Ξ

E

Blandford-Znajek efficiency

 $\eta_{\rm BZ}$ depends on:

- BH spin, $a_{\rm BH}^2$
- disk magnetization, σ
- poloidal/toroidal field (only $B_{\rm pol}$ is used) [see Liska et al. 2020 for a recent discussion]
- extent of force-free region ("disk occultation effect") [Tchekhovskoy et al. 2010]

Maximum efficiency: Magnetically Arrested Disk, $\eta_{\rm BZ,MAD}\gtrsim 1$ [Bisnovatyi-Kogan & Ruzmaikin '74; Narayan et al.'03]

 $\eta_{\rm BZ}$ as low as 10^{-3} if thick disk & predominantly toroidal B [see Salafia & Giacomazzo 2020 for a recent discussion]

2024-08-01

< □ ▶

Summary 1

- Gamma-ray bursts produced in relativistic jets; some from aftermath of binary neutron star mergers
- Blandford-Znajek process (spinning BH + magnetized accretion disk) main jet-launching mechanism candidate
- proto-NS central engine not ruled out yet
- if jet driven by accretion, efficiency not very high: in Blandford-Znajek setting, this implies predominantly toroidal magnetic field right after merger;
- to produce observable emission, the jet must break out from the ejecta cloud. In doing so it is reshaped and it deposits part of its energy in a cocoon
- prompt emission mechanism not well understood: magnetic vs kinetic? sub-photospheric vs optically thin dissipation?
- afterglow produced in shock that arises as the jet expands into ISM;

Summary 2

- GW170817 prompted huge improvement in understanding of GRB jets (e.g. superluminal motion confirmed relativistic and collimated nature; role of jet structure highlighted);
- GW-GRB delay in GW170817 may indicate long-lived neutron star, but may also be just dominated by propagation effects
- GW170817 jet is only known example of a clearly off-axis GRB jet

Thank you!
