### Extrapolation and emulation techniques for few-body resonances

### Sebastian König

**Next-Generation Ab Initio Nuclear** 

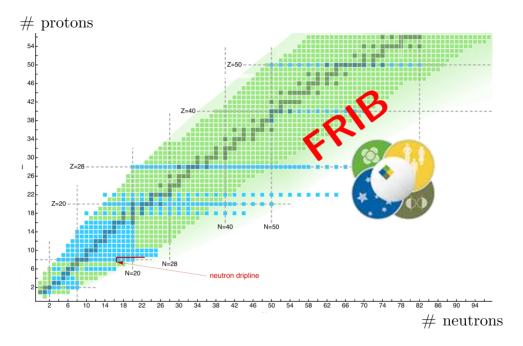

ECT\*, Trento, July 15, 2025

Yapa, Fossez, SK, PRC 107 064316 (2023); PRC 111 064318 (2025)

## **Motivation**

original chart: Hergert et al., Phys. Rep. 621 165 (2016)

- rare isotope facilities will discover unknown nuclei near the edge of stability
  - among those there are likely exotic states
  - halos, clusters ~> few-body resonances

Resonances

**Eigenvector Continuation** 

**Complex Scaling Method** 

All above combined

### Resonances

### Intuitive

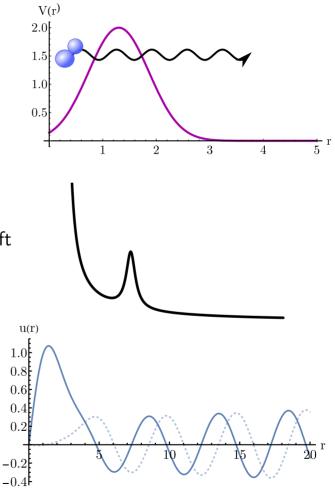

- metastable state (finite lifetime)
- tunneling through potential barrier

### Experimentally

- peak in cross section
- related to sharp jump in scattering phase shift  $\Gamma^2$
- $ullet \ \sigma \sim rac{\Gamma^2}{(E-E_R)^2+\Gamma^2/4}$

### Formally

- S-matrix pole at complex energy
- wave function similar to bound state...
- ...but not quite normalizable

## **Eigenvector continuation**

#### Many physics problems are tremendously difficult...

- huge matrices, possibly too large to store
  - ever more so given the evolution of typical HPC clusters
- most exact methods suffer from exponential scaling
- interest only in a few (lowest) eigenvalues

Martin Grandjean, via Wikimedia Commons (CC-AS 3.0)

#### Introducing eigenvector continuation

D. Lee, TRIUMF Ab Initio Workshop 2018; Frame et al., PRL 121 032501 (2018)

- novel numerical technique, broadly applicable
  - ▶ emulators, perturbation theory, ...

Duguet, Ekström, Furnstahl, SK, Lee, RMP 96 031002 (2024)

- amazingly simple in practice
- special case of "reduced basis method" (RBM)

Bonilla et al., PRC 106 054322 (2022); Melendez et al., JPG 49 102001 (2022)

KDE Oxygen Theme

## Eigenvector continuation 101

### Scenario

Frame et al., PRL **121** 032501 (2018)

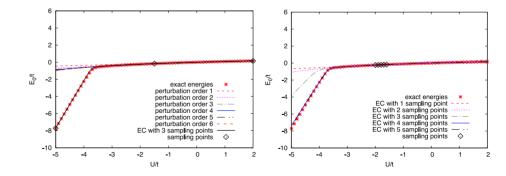

- consider physical state (eigenvector) in a large space
- parametric dependence of Hamiltonian H(c) traces only small subspace
- prerequisite: smooth dependence of H(c) on c (or  $\vec{c}$ )
- enables analytic continuation of  $\ket{\psi(c)}$  from  $c_{ ext{train}}$  to  $c_{ ext{target}}$

#### Procedure

- calculate  $|\psi(c_i)
  angle$  ,  $i=1,\ldots N_{
  m EC}$  in "training regime"
- solve generalized eigenvalue problem  $H|\psi
  angle=\lambda N|\psi
  angle$  with
  - $\blacktriangleright H_{ij} = \langle \psi_i | H(c_{\mathrm{target}}) | \psi_j \rangle$
  - $\blacktriangleright N_{ij} = \langle \psi_i | \psi_j \rangle$

#### Example

- Hubbard model
- c = U/t

• large number of applications/extensions in recent years!

Duguet, Ekström, Furnstahl, SK, Lee, RMP 96 031002 (2024)

## Need for emulators

#### 1. Fitting of LECs to few- and many-body observables

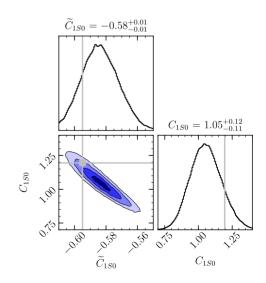

- common practice now to use A>3 to **constrain nuclear forces**, e.g.:
  - ▶ JISP16, NNLO<sub>sat</sub>,  $\alpha$ - $\alpha$  scattering

Shirokov et al., PLB 644 33 (2007); Ekström et al., PRC 91 051301 (2015); Elhatisari et al., PRL 117 132501 (2016)

• fitting needs many calculations with different parameters

#### 2. Propagation of uncertainties

- statistical fitting gives posteriors for LECs
- LEC uncertainties propagate to observables
  - typically achieved via Bayesian statistics
     Wesolowski et al., JPG 46 045102 (2019)
- need to sample a large number of calculations
  - expensive already in few-body sector
  - typically not doable for many-body problems!

### Hamiltonian parameter spaces

• Consider a Hamiltonian depending on several parameters:

$$H = H_0 + V = H_0 + \sum_{k=1}^d c_k V_k$$
 (1)

- ▶ in particular, V can be a chiral potential with LECs  $c_k$
- ► Hamiltonian is element of *d*-dimensional parameter space
- convenient notation:  $ec{c} = \{c_k\}_{k=1}^d$
- ▶ typical for  $\mathcal{O}(Q^3)$  potential: 14 two-body LECs + 2 three-body LECs

### **EC** emulation

SK, A. Ekström, K. Hebeler, D. Lee, A. Schwenk, PLB 810 135814 (2020), ...

- EC can accomodate multi-dimensional parameter spaces  $(c_i 
  ightarrow ec{c}_i)$ 
  - $ullet \left|\psi_{i}
    ight
    angle = \left|\psi(ec{c}_{i})
    ight
    angle$  for  $i=1,\cdot\cdot N_{ ext{EC}}$
  - ullet  $H_{ij}=\langle\psi_i|H(ec{c}_{ ext{target}})|\psi_j
    angle$ ,  $N_{ij}=\langle\psi_i|\psi_j
    angle$
- the sum in Eq. (1) can be carried out in small (dimension  $= N_{
  m EC}$ ) space!
  - ▶ this permits an offline/online decomposition of the problem
- generally highly efficient and accurate

## Many more EC applications, e.g.:

- Many-body perturbation theory Demol, SK, et al., PRC 101 041302(R) (2020)
- Two- and three-body scattering Melendez et al. PLB (2021); Drischler et al. PLB (2021); Zhang + Furnstahl (2022)
- Volume extrapolation Yapa + SK, PRC 106 014309 (2022)
- Shell-model emulators Yoshida+Shimizu, PTEP 2022 053D02 (2022)
- ... Duguet, Ekström, Furnstahl, SK, Lee, RMP **96** 031002 (2024)

### Now back to resonances...

### Formal look at resonances

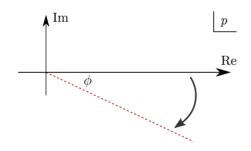

- in stationary scattering theory, resonances are described as generalized eigenstates
  - S-matrix poles at comples energies  $E=E_R-\mathrm{i}\Gamma/2$  (lifetime  $\sim 1/\Gamma$ )
  - ▶ wave functions are not normalizable (exponentially growing in *r*-space)

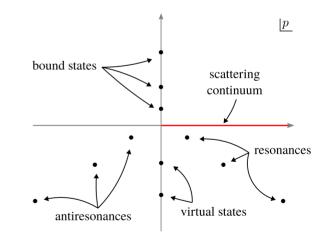

#### **Complex scaling method**

• one way to circumvent this problem is the complex scaling method:

$$r 
ightarrow {
m e}^{{
m i} \phi} r \;\;,\;\;\; p 
ightarrow {
m e}^{-{
m i} \phi} p$$

 $\rightsquigarrow$  "reveals" the resonance regime

## Complex-scaled resonance wave functions

• complex scaling suppresses the exponentially growing tail of the wave function

calculations by Nuwan Yapa

### Formal look at resonances

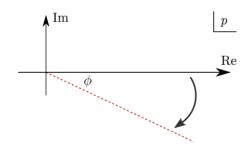

- in stationary scattering theory, resonances are described as generalized eigenstates
  - S-matrix poles at comples energies  $E=E_R-\mathrm{i}\Gamma/2$  (lifetime  $\sim 1/\Gamma$ )
  - ▶ wave functions are not normalizable (exponentially growing in *r*-space)

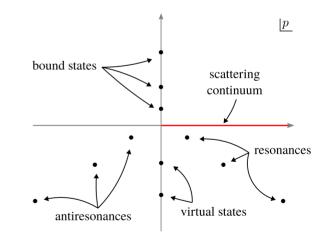

#### **Complex scaling method**

• one way to circumvent this problem is the complex scaling method:

$$r 
ightarrow {
m e}^{{
m i} \phi} r \;\;,\;\;\; p 
ightarrow {
m e}^{-{
m i} \phi} p$$

 $\rightsquigarrow$  "reveals" the resonance regime

### Formal look at resonances

- in stationary scattering theory, resonances are described as generalized eigenstates
  - S-matrix poles at comples energies  $E=E_R-\mathrm{i}\Gamma/2$  (lifetime  $\sim 1/\Gamma$ )
  - ▶ wave functions are not normalizable (exponentially growing in *r*-space)

#### **Complex scaling method**

• one way to circumvent this problem is the complex scaling method:

#### Notes

- this particular method is also called "uniform" complex scaling
- essentially, one uses a basis of complex momentum modes

## EC for resonances

### Why?

- LEC fitting and/or observable predictions may include unstable states
  - ► accurate and efficient resonance emulators are needed for this
  - ▶ especially in the few-body sector, where calculations rapidly become expensive
- but there is also an important technical reason:
  - ► basis expansion methods are typically good for targeting extremal eigenvalues
  - Lanczos/Arnoldi iteration and related techniques
  - complex physical resonance eigenvalues can be difficult to identify
  - ▶ bound states, on the other hand, are easy to find
  - tracking a state from being bound to becoming unbound can help!

## EC for resonances

### Why?

- LEC fitting and/or observable predictions may include unstable states
  - accurate and efficient resonance emulators are needed for this
  - ▶ especially in the few-body sector, where calculations rapidly become expensive
- but there is also an important technical reason:
  - ► basis expansion methods are typically good for targeting extremal eigenvalues
  - Lanczos/Arnoldi iteration and related techniques
  - complex physical resonance eigenvalues can be difficult to identify
  - ▶ bound states, on the other hand, are easy to find
  - tracking a state from being bound to becoming unbound can help!

### How?

- combine EC with complex scaling, work with complex eigenvalues
- formalism needs to be developed/adapted for this task

Yapa, Fossez, SK, PRC 107 064316 (2023); PRC 111 064318 (2025)

• related work discusses other extension of EC to non-Hermitian systems

see e.g. Zhang, 2408.03309 [nucl-th], 2411.06712 [nucl-th]; Cheng et al., 2411.15492 [nucl-th]

### One important detail

• under complex scaling, the Hamiltonian becomes non-Hermitian

$$r 
ightarrow {
m e}^{{
m i} \phi} r \;\;,\;\;\; p 
ightarrow {
m e}^{-{
m i} \phi} p \;\;\; \rightsquigarrow H = H^*$$

- ► instead, it becomes complex symmetric
- ► as such, it can have complex eigenvalues ✓
- this changes the inner product between states

$$\langle \phi | \psi 
angle = \int \mathrm{d}r \, \phi(r) \psi(r)$$

- no complex conjugation for bra-side states
- this is called the "c-product"
- ▶ physical states with different energies are orthogonal w.r.t. c-product

Moiseyev, Certain, Weinhold, Mol. Phys. 36 1613 (1978)

## One important detail

• under complex scaling, the Hamiltonian becomes non-Hermitian

$$r 
ightarrow {
m e}^{{
m i} \phi} r \;\;,\;\;\; p 
ightarrow {
m e}^{-{
m i} \phi} p \;\;\; \leadsto H = H^*$$

- ► instead, it becomes complex symmetric
- ► as such, it can have complex eigenvalues ✓
- this changes the inner product between states

$$\langle \phi | \psi 
angle = \int \mathrm{d}r \, \phi(r) \psi(r)$$

- no complex conjugation for bra-side states
- this is called the "c-product"
- ▶ physical states with different energies are orthogonal w.r.t. c-product

Moiseyev, Certain, Weinhold, Mol. Phys. 36 1613 (1978)

#### Note

- bound-state energies remain invariant under complex scaling
- but the c-product is still needed in the non-Hermitian framework

### **Resonance-to-resonance continuation**

- for resonance to-resonance continuation, EC works directly...
- ...if one simply uses the c-product for all matrix elements

Yapa, Fossez, SK, PRC 107 064316 (2023)

## Eigenvector continuation 101

### Scenario

Frame et al., PRL **121** 032501 (2018)

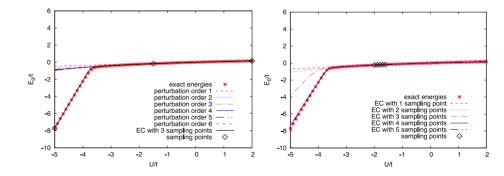

- consider physical state (eigenvector) in a large space
- parametric dependence of Hamiltonian H(c) traces only small subspace
- prerequisite: smooth dependence of H(c) on c (or  $\vec{c}$ )
- enables analytic continuation of  $\ket{\psi(c)}$  from  $c_{ ext{train}}$  to  $c_{ ext{target}}$

### Procedure

- calculate  $|\psi(c_i)
  angle$  ,  $i=1,\ldots N_{
  m EC}$  in "training regime"
- solve generalized eigenvalue problem  $H|\psi
  angle=\lambda N|\psi
  angle$  with
  - $\blacktriangleright H_{ij} = \langle \psi_i | H(c_{\mathrm{target}}) | \psi_j \rangle$
  - $\blacktriangleright N_{ij} = \langle \psi_i | \psi_j \rangle$

### Example

- Hubbard model
- c = U/t

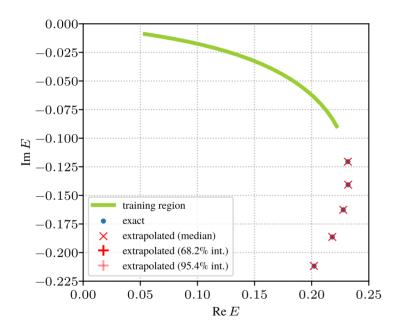

• large number of applications/extensions in recent years!

Duguet, Ekström, Furnstahl, SK, Lee, RMP 96 031002 (2024)

### **Resonance-to-resonance continuation**

- for resonance to-resonance continuation, EC works directly...
- ...if one simply uses the c-product for all matrix elements

Yapa, Fossez, SK, PRC **107** 064316 (2023)

momentum-space two-body calculation

$$V(c;r) = c \left[ -5 \mathrm{e}^{-r^2/3} + 2 \mathrm{e}^{-r^2/10} 
ight]$$

- sampled points within training regime
- repeated EC evaluation with 5 points
- benchmark against exact result
- excellent agreement

### **Resonance-to-resonance continuation**

- for resonance to-resonance continuation, EC works directly...
- ...if one simply uses the c-product for all matrix elements

0.000-0.025-0.050-0.075= -0.100 - 125 - 0.1× -0.125× -0.150training region × -0.175extrapolated (median) × -0.200extrapolated (68.2% int.) extrapolated (95.4% int.) -0.225-0.050.100.150.200.000.25 $\operatorname{Re} E$ 

Yapa, Fossez, SK, PRC 107 064316 (2023)

momentum-space two-body calculation

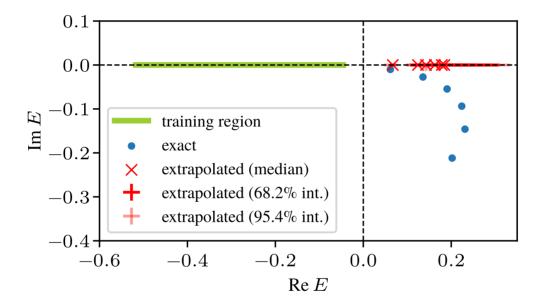

$$V(c;r) = c \left[ -5 \mathrm{e}^{-r^2/3} + 2 \mathrm{e}^{-r^2/10} 
ight]$$

- sampled points within training regime
- repeated EC evaluation with 5 points
- benchmark against exact result
- excellent agreement

- Note: in the plot, we only show benchmarks for EC extrapolation
  - ► that is because interpolation is generally much easier
  - ▶ for resonance emulators, both are relevant and needed

### Bound-state-to-resonance continuation

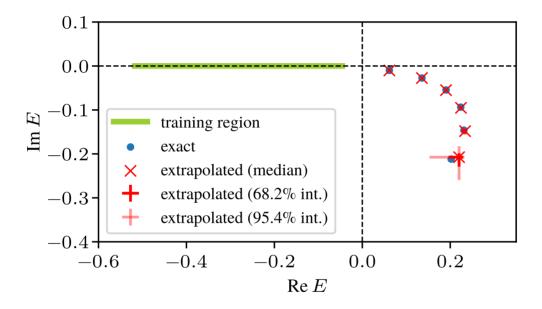

• bound-state-to-resonance extrapolation fails with naive approach...

- it can be shown that for bound states, the EC Hamiltonian is real symmetric
  - ▶ this is a consequence of using the c-product for complex-scaled bound states
  - ► as such, it can have only real eigenvalues

### Bound-state-to-resonance continuation

• however, there is a way to make this work!

- we introduced complex-augmented eigenvector continuation (CA-EC)
  - ▶ in addition to the training wave functions, include also their complex conjugates
  - ▶ this provides the key information to describe the long-distance asymptotics
  - doubles EC basis size at (almost) zero cost

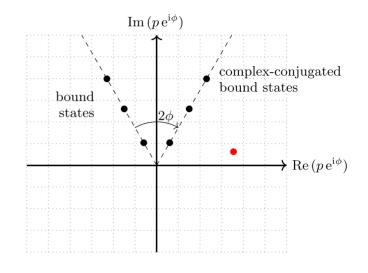

Yapa, Fossez, SK, PRC 107 064316 (2023)

### Why does this work?

# Complex-augmented EC

#### Intuitive explanation

- bound-state energies CS-invariant
- but asymptotic wave numbers change
- complex conjugation moves them into the right quadrant for describing resonances

#### **Formal explanation**

- consider the Schrödinger equation for the complex-conjugated bound state
- evalulate it at large distances, where the potential becomes negligible:

$$-\mathrm{e}^{2\mathrm{i}\phi}rac{
abla^2}{2\mu}\psi(\mathbf{r})=E\,\psi(\mathbf{r})\quad ext{for}\quad |\mathbf{r}| o\infty$$

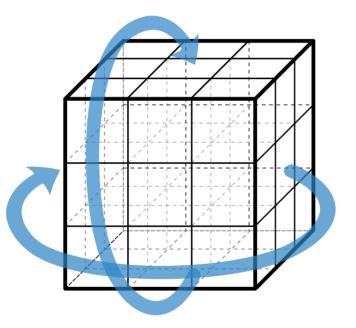

• multiplication with  ${
m e}^{-4{
m i}\phi}$  yields  $H_\phi\psi^*({f r})={
m e}^{-4{
m i}\phi}E\,\psi^*({f r})$ 

Yapa, SK, Fossez, PRC 111 064318 (2025)

## What about more than two particles?

Benchmark different few-/many-body methods

**Consider a cubic peridioc boundary condition:** 

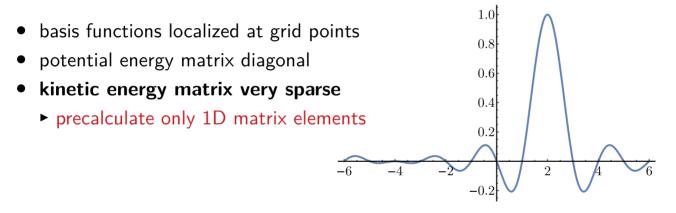

- useful to directly extract observables from volume dependence of energy levels
  - asymptotic normalization coefficients, resonance positions, radii ..., Yu, SK, Lee, PRL 131 212502 (2023); Klos, SK el al., PRC 98 034004 (2018); Taurence + SK, PRC 109 054315 (2024)
- but also as a generic and powerful few-body technique

### **Discrete variable representation**

#### Efficient calculation of few-body energy levels

• use a Discrete Variable Representation (DVR)

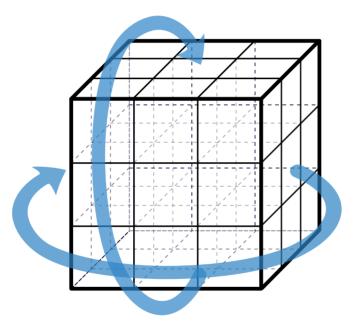

well established in quantum chemistry, suggested for nuclear physics by Bulgac+Forbes, PRC 87 051301 (2013)

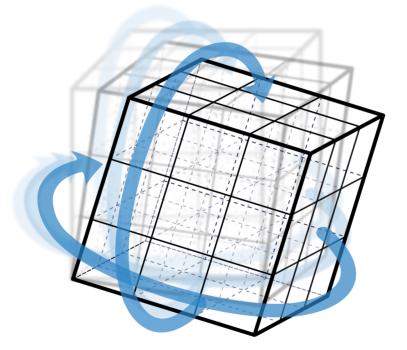

- periodic boundary condistions  $\leftrightarrow$  plane waves as starting point
- efficient implementation for large-scale calculations
  - handle arbitrary number of particles (and spatial dimensions)
  - ▶ numerical framework scales from laptop to HPC clusters Klos, SK et al., PRC 98 034004 (2018)
  - ► recent extensions: GPU acceleration, separable interactions

Dietz, SK et al., PRC 105 064002 (2022); SK, JP Conf. Ser. 2453 012025 (2023)

**Consider a cubic peridioc boundary condition:** 

#### **Consider a cubic peridioc boundary condition:**

#### Now imagine it in terms of complex-scaled coordinates!

### Key idea

Yu, Yapa, SK, PRC **109** 014316 (2023)

• put system into a box, apply peridioc boundary condition along rotated axes

#### **Volume dependence**

- resonances, like bound states, correspond to isolated S-matrix poles
- complex scaling renders their wave functions normalizable
- we can adapt bound-state techniques to derive their volume dependence

$$\Delta E(L) = rac{3\gamma_\infty^2}{\mu\zeta L} \Bigg[ rac{\exp(\mathrm{i}\zeta p_\infty L) + \sqrt{2}\mathrm{exp}(\mathrm{i}\sqrt{2}\zeta p_\infty L) + rac{4\exp(\mathrm{i}\zeta\sqrt{3}p_\infty L)}{3\sqrt{3}L} \Bigg] + \mathcal{O}\left(\mathrm{e}^{\mathrm{i}2\zeta p_\infty L}
ight)$$

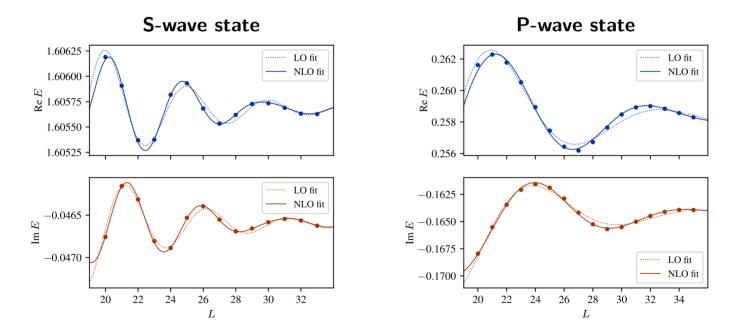

- in this equation  $\zeta = {
  m e}^{{
  m i}\phi}$  ,  $p_\infty = \sqrt{2\mu E(\infty)}$
- explicit form for leading term (LO) and subleading corrections (NLO)
- note: dependence on volume L and complex-scaling angle  $\phi$

#### Numerical implementation

• DVR method can be adapted to this scenario (scaling of  $x, y, z \rightsquigarrow$  scaling of r)

### **Resonance examples**

- two-body calculations are in excellent agreement with derived volume dependence
  - ► S-wave resonance generated via explicit barrier
  - P-wave resonance from purely attractive potential

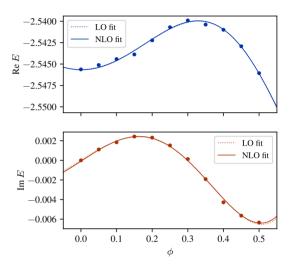

• fitting the *L* dependence yields physical resonance position and lifetime!

## More applications

### Single-volume bound-state fitting

- bound-state energies normally remain real under complex scaling (strictly true in infinite volume)
- the finite-volume, however, induces a non-zero imaginary part
- $\operatorname{Re} E$  and  $\operatorname{Im} E$  oscillate as a function of L
  - $\blacktriangleright$  and also as a function of  $\phi$
- possible to fit  $\phi$  dependence at fixed volume!

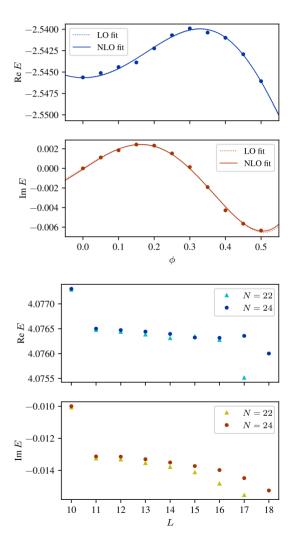

## More applications

### Single-volume bound-state fitting

- bound-state energies normally remain real under complex scaling (strictly true in infinite volume)
- the finite-volume, however, induces a non-zero imaginary part
- $\operatorname{Re} E$  and  $\operatorname{Im} E$  oscillate as a function of L
  - $\blacktriangleright$  and also as a function of  $\phi$
- possible to fit  $\phi$  dependence at fixed volume!

### Three-body resonance

- the exact volume dependence is only known for two-body system
- the complex scaled FV-DVR can however be used to study more particles
- three-boson example in good agreement with previous avoided-crossings analysis
   Klos, SK et al., PRC 98 034004 (2018)

### Three-boson resonance trajectory

- take potential from before that generates a (genuine) three-body resonance
  - established via avoided level crossings (purely real spectrum)
- add attractive two-body potential to bind system Klos, SK et al., PRC 98 034004 (2018)
- use eigenvector continuation (via complex scaling in FV) to extrapolate

$$Im E$$

$$-1 \bigoplus_{2}^{1.9} \bigoplus_{1.8}^{1.6} \bigoplus_{1.5}^{1.41} \bigoplus_{1.3}^{1.2} \bigoplus_{1.1}^{2} \bigoplus_{0.9}^{2} \bigoplus_{0.8}^{0.6} \bigoplus_{0.7}^{0.6} \bigoplus_{0.6}^{0.5} \bigoplus_{0.3}^{0.6} \bigoplus_{0.2}^{0.8} \bigoplus_{0.1}^{0.1} \bigoplus_{0.2}^{0.1} \bigoplus_{0.1}^{1.1} \bigoplus_{0.2}^{1.1} \bigoplus_{0.1}^{1.2} \bigoplus_{0.1}^{$$

$$V(r)=2\expigg[-\left(rac{r-3}{1.5}
ight)igg]+V_0\expigg(-(r/3)^2ig)$$

# Resonance EC for few/many-body systems

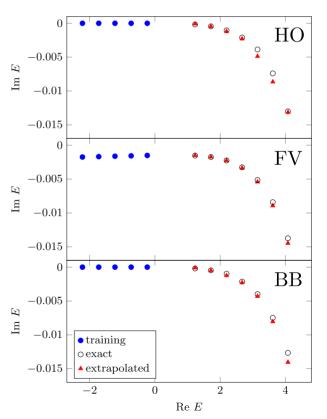

#### **CA-EC** can be implemented with different numerical methods:

• Finite-Volume (FV) DVR

- ► just discussed
- Harmonic Oscillator (HO) basis (complex freq.)
  - equivalent to complex scaling
- Berggren Basis (BB)
  - deformed contour plus selection of poles
- Gamow Shell Model
  - path towards many-body applications

### **Comparison / Benchmark**

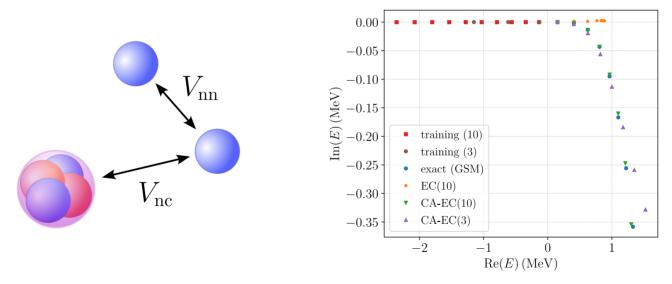

- three-boson system with...
  - ► HO basis
  - ► FV-DVR calculation
  - ► Berggren Basis
- ~> excellent agreement overall!

Yapa, SK, Fossez, PRC 111 064318 (2025)

## Realistic physics application

- consider Gamow Shell Model (GSM) for <sup>6</sup>He system
  - ► <sup>4</sup>He core plus two neutrons
  - Woods-Saxon potential for core-neutron interaction, fit to  ${}^{4}\text{He-}n$  phase shifts
  - contact interaction between neutrons
- reduce strength of *nn* interaction to make system unbound

CA-EC works nicely also for this system!

Yapa, SK, Fossez, PRC **111** 064318 (2025)

Fossez et al., PRC **98** 061302 (2018)

## Conclusion

### Summary

- complex scaling method can be combined with eigenvector continuation
- possible to construct emulators for resonance states
- resonance-to-resonance extrapolation is straightforward
- conjugate-augmented EC enables **bound-state-to-resonance** extrapolation
- method initially developed for two-body resonances
- extension to three-body resonances recently established
- method works independent of particular numerical framework
- GSM application paves way towards extrapolating many-body resonances

### Outlook

- inclusion of Coulomb force important to treat charged-particles resonances
- $\bullet\,$  application to recently discoverd exotic resonances, such as  $^9{\rm N}$
- consider possible extensions to handle virtual ("anti-bound") states
